

User and Reference Manual: All Parts

Release 3.2.1

13 July 2006

Internal Release 3.2.1-I-21

Contents

I	General Introduction	1
1	General Introduction	3
1.1	License Issues	3
1.2	Third Party Software	5
1.3	Advanced	6
1.4	Namespace CGAL	6
1.5	Inclusion Order of Header Files	7
1.6	Compile-time Flags to Control Inlining	7
1.7	Checks	7
II	Kernels	11
2	2D and 3D Kernel	13
2.1	Introduction	13
2.2	Kernel Representations	14
2.3	Kernel Geometry	17
2.4	Predicates and Constructions	18
2.5	Extensible Kernel	21
2.6	Kernel Related Tools	27
	Reference Manual	31
2.7	Concepts	35
2.8	Kernel Classes and Operations	41

2.9	Predefined Kernels	57
2.10	Kernel Objects	60
2.11	Constants and Enumerations	123
2.12	Global Functions	135
2.13	Kernel Function Object Concepts	207
2.14	Tag Classes	426
3	dD Kernel	427
3.1	Introduction	427
3.2	Kernel Representations	428
3.3	Kernel Geometry	431
3.4	Predicates and Constructions	432
	Reference Manual	435
3.5	Linear Algebra Concepts and Classes	437
3.6	Kernel Objects	447
3.7	Global Kernel Functions	477
3.8	Kernel Concept	499
4	2D Circular Kernel	533
4.1	Introduction	533
4.2	Software Design	533
4.3	Examples	534
4.4	Design and Implementation History	538
	Reference Manual	541
4.5	Geometric Concepts	541
4.6	Algebraic Concepts	542
4.7	Geometric Kernels and Classes	542
4.8	Algebraic Kernel and Classes	543
4.9	Traits Classes for CGAL Arrangements	543
4.10	Alphabetical List of Reference Pages	543

III	Convex Hull Algorithms	607
5	2D Convex Hulls and Extreme Points	609
5.1	Introduction	609
5.2	Convex Hull	610
5.3	Example using Graham-Andrew's Algorithm	610
5.4	Extreme Points and Hull Subsequences	611
5.5	Traits Classes	611
5.6	Convexity Checking	612
	Reference Manual	613
5.7	Classified Reference Pages	613
5.8	Alphabetical List of Reference Pages	615
6	3D Convex Hulls	655
6.1	Introduction	655
6.2	Static Convex Hull Construction	655
6.3	Incremental Convex Hull Construction	657
6.4	Dynamic Convex Hull Construction	659
	Reference Manual	661
6.5	Classified Reference Pages	661
6.6	Alphabetical List of Reference Pages	663
7	dD Convex Hulls and Delaunay Triangulations	681
7.1	Introduction	681
7.2	dD Convex Hull	681
7.3	Delaunay Triangulation	682
	Reference Manual	683
7.4	Classified Reference Pages	683
7.5	Alphabetical List of Reference Pages	684

IV Polygons and Polyhedra	707
8 2D Polygons	709
8.1 Introduction	709
8.2 Example	709
Reference Manual	713
8.3 Classified Reference Pages	713
8.4 Alphabetical List of Reference Pages	714
9 2D Polygon Partitioning	735
9.1 Introduction	735
9.2 Monotone Partitioning	735
9.3 Convex Partitioning	736
Reference Manual	737
9.4 Classified Reference Pages	737
9.5 Alphabetical List of Reference Pages	738
10 3D Polyhedral Surfaces	781
10.1 Introduction	781
10.2 Definition	782
10.3 Example Programs	782
10.4 File I/O	789
10.5 Extending Vertices, Halfedges, and Facets	790
10.6 Advanced Example Programs	792
Reference Manual	797
10.7 Classified Reference Pages	797
10.8 Alphabetical List of Reference Pages	798
11 Halfedge Data Structures	835
11.1 Introduction	835
11.2 Software Design	836

11.3	Example Programs	837
	Reference Manual	845
11.4	Classified Reference Pages	845
11.5	Alphabetical List of Reference Pages	846
V	Polygon and Polyhedron Operations	893
12	2D Regularized Boolean Set-Operations	895
12.1	Introduction	895
12.2	Boolean Set-Operations on Linear Polygons	896
12.3	Boolean Set-Operations on General Polygons	906
	Reference Manual	915
12.4	Classified Reference Pages	915
12.5	Alphabetical List of Reference Pages	916
13	2D Boolean Operations on Nef Polygons	953
13.1	Introduction	953
13.2	Construction and Composition	954
13.3	Exploration	955
13.4	Traits Classes	956
13.5	Implementation	956
	Reference Manual	959
13.6	Classified Reference Pages	959
13.7	Alphabetical List of Reference Pages	959
14	2D Boolean Operations on Nef Polygons Embedded on the Sphere	981
14.1	Introduction	981
14.2	Restricted Spherical Geometry	982
14.3	Example Programs	983
	Reference Manual	989
14.4	Classified Reference Pages	989

14.5	Alphabetical List of Reference Pages	989
15	3D Boolean Operations on Nef Polyhedra	1011
15.1	Introduction	1011
15.2	Definition	1012
15.3	Infimaximal Box	1015
15.4	Regularized Set Operations	1015
15.5	Example Programs	1016
15.6	File I/O	1021
15.7	Further Example Programs	1022
15.8	Visualization	1026
	Reference Manual	1031
15.9	Classified Reference Pages	1031
15.10	Alphabetical List of Reference Pages	1032
16	2D Straight Skeleton and Polygon Offsetting	1057
16.1	Definitions	1057
16.2	Representation	1063
16.3	API	1066
16.4	Straight Skeletons, Medial Axis and Voronoi Diagrams	1071
16.5	Usages of the Straight Skeletons	1072
16.6	Straight Skeleton of a General Figure in the Plane	1072
	Reference Manual	1073
16.7	Classified Reference Pages	1073
16.8	Alphabetical List of Reference Pages	1073
VI	Arrangements	1101
17	2D Arrangements	1103
17.1	Introduction	1104
17.2	The Main Arrangement Class	1105

17.3	Issuing Queries on an Arrangement	1121
17.4	Free Functions in the Arrangement Package	1129
17.5	Traits Classes	1137
17.6	The Notification Mechanism	1163
17.7	Extending the DCEL	1167
17.8	Overlaying Arrangements	1172
17.9	Storing the Curve History	1177
17.10	Input/Output Functions	1183
17.11	Adapting to BOOST Graphs	1189
17.12	How To Speed Up Your Computation	1194
	Reference Manual	1197
17.13	Classified Reference Pages	1197
17.14	Alphabetical List of Reference Pages	1199
18	2D Intersection of Curves	1329
18.1	Introduction	1329
	Reference Manual	1333
18.2	Alphabetical List of Reference Pages	1333
19	2D Snap Rounding	1337
19.1	Introduction	1337
19.2	What is Snap Rounding/Iterated Snap Rounding	1338
19.3	Terms and Software Design	1338
19.4	Four Line Segment Example	1338
	Reference Manual	1341
19.5	Alphabetical List of Reference Pages	1341
VII	Triangulations and Delaunay Triangulations	1349
20	2D Triangulations	1351
20.1	Definitions	1352

20.2	Representation	1353
20.3	Software Design	1354
20.4	Basic Triangulations	1356
20.5	Delaunay Triangulations	1359
20.6	Regular Triangulations	1361
20.7	Constrained Triangulations	1364
20.8	Constrained Delaunay Triangulations	1365
20.9	Constrained Triangulations Plus	1367
20.10	The Triangulation Hierarchy	1368
20.11	Flexibility: Using Customized Vertices and Faces	1371
20.12	Design and Implementation History	1374
	Reference Manual	1375
20.13	Classified Reference Pages	1375
20.14	Alphabetical List of Reference Pages	1376
21	2D Triangulation Data Structure	1455
21.1	Definition	1455
21.2	The Concept of Triangulation Data Structure	1456
21.3	The Default Triangulation Data Structure	1457
	Reference Manual	1461
21.4	Classified Reference Pages	1461
21.5	Alphabetical List of Reference Pages	1462
22	3D Triangulations	1485
22.1	Representation	1486
22.2	Delaunay Triangulation	1487
22.3	Regular Triangulation	1488
22.4	Triangulation Hierarchy	1488
22.5	Software Design	1489
22.6	Examples	1493

22.7	Design and Implementation History	1500
	Reference Manual	1501
22.8	Classified Reference Pages	1501
22.9	Alphabetical List of Reference Pages	1502
23	3D Triangulation Data Structure	1561
23.1	Representation	1561
23.2	Software Design	1564
23.3	Examples	1567
23.4	Design and Implementation History	1570
	Reference Manual	1571
23.5	Classified Reference Pages	1571
23.6	Alphabetical List of Reference Pages	1572
24	2D Alpha Shapes	1599
24.1	Definitions	1600
24.2	Functionality	1600
24.3	Concepts and Models	1601
24.4	Examples	1601
	Reference Manual	1603
24.5	Classified Reference Pages	1603
24.6	Alphabetical List of Reference Pages	1604
25	3D Alpha Shapes	1619
25.1	Definitions	1621
25.2	Functionality	1622
25.3	Concepts and Models	1622
25.4	Examples	1623
	Reference Manual	1627
25.5	Classified Reference Pages	1628
25.6	Alphabetical List of Reference Pages	1628

VIII	Voronoi Diagrams	1645
26	2D Segment Delaunay Graphs	1647
26.1	Definitions	1647
26.2	Software Design	1649
26.3	The Geometric Traits	1652
26.4	The Segment Delaunay Graph Hierarchy	1653
26.5	Examples	1654
	Reference Manual	1659
26.6	Classified Reference Pages	1659
26.7	Alphabetical List of Reference Pages	1660
27	2D Apollonius Graphs (Delaunay Graphs of Disks)	1699
27.1	Definitions	1699
27.2	Software Design	1701
27.3	The Geometric Traits	1702
27.4	The Apollonius Graph Hierarchy	1705
27.5	Examples	1705
	Reference Manual	1711
27.6	Classified Reference Pages	1711
27.7	Alphabetical List of Reference Pages	1712
28	2D Voronoi Diagram Adaptor	1739
28.1	Introduction	1739
28.2	Software Design	1741
28.3	The Adaptation Traits	1742
28.4	The Adaptation Policy	1743
28.5	Examples	1745
	Reference Manual	1749
28.6	Classified Reference Pages	1749
28.7	Alphabetical List of Reference Pages	1750

IX	Meshing	1785
29	2D Conforming Triangulations and Meshes	1787
29.1	Conforming Triangulations	1787
29.2	Meshes	1791
	Reference Manual	1799
29.3	Classified Reference Pages	1799
29.4	Alphabetical List of Reference Pages	1799
30	3D Surface Mesher	1821
30.1	Introduction	1822
30.2	The Surface Mesher Interface	1822
30.3	Examples	1823
30.4	Meshing Criteria, Guarantees and Variations	1826
30.5	Design and Implementation History	1827
	Reference Manual	1829
30.6	Classified Reference Pages	1829
30.7	Alphabetical List of Reference Pages	1830
31	3D Surface Subdivision Methods	1867
31.1	Introduction	1867
31.2	Subdivision Method	1868
31.3	A Quick Example: Catmull-Clark Subdivision	1869
31.4	Catmull-Clark Subdivision	1870
31.5	Refinement Host	1873
31.6	Geometry Policy	1874
31.7	The Four Subdivision Methods	1876
31.8	Other Subdivision Methods	1877
	Reference Manual	1881
31.9	Classified Reference Pages	1881
31.10	Alphabetical List of Reference Pages	1881

32 Planar Parameterization of Triangulated Surface Meshes	1895
32.1 Introduction	1896
32.2 Basics	1897
32.3 Surface Parameterization Methods	1902
32.4 Sparse Linear Algebra	1908
32.5 Cutting a Mesh	1909
32.6 Output	1914
32.7 Complexity and Guarantees	1920
32.8 Software Design	1922
32.9 Extending the Package and Reusing Code	1926
Reference Manual	1929
32.10 Classified Reference Pages	1929
32.11 Alphabetical List of Reference Pages	1932
 X Search Structures	 2005
 33 2D Search Structures	 2007
33.1 Introduction	2007
33.2 Examples	2008
Reference Manual	2011
33.3 Classified Reference Pages	2011
33.4 Alphabetical List of Reference Pages	2011
 34 Interval Skip List	 2025
34.1 Definition	2025
34.2 Example Programs	2025
Reference Manual	2029
34.3 Classified Reference Pages	2029
34.4 Alphabetical List of Reference Pages	2029

35 dD Spatial Searching	2037
35.1 Introduction	2037
35.2 Splitting Rules	2039
35.3 Example Programs	2039
35.4 Software Design	2049
Reference Manual	2051
35.5 Classified Reference Pages	2051
35.6 Alphabetical List of Reference Pages	2052
 36 dD Range and Segment Trees	 2109
36.1 Introduction	2109
36.2 Definitions	2109
36.3 Software Design	2110
36.4 Creating an Arbitrary Multilayer Tree	2113
36.5 Range Trees	2113
36.6 Segment Trees	2115
Reference Manual	2119
36.7 Classified Reference Pages	2119
36.8 Alphabetical List of Reference Pages	2120
 37 Intersecting Sequences of dD Iso-oriented Boxes	 2147
37.1 Introduction	2147
37.2 Definition	2148
37.3 Software Design	2148
37.4 Minimal Example for Intersecting Boxes	2149
37.5 Example for Finding Intersecting 3D Triangles	2150
37.6 Example for Using Pointers to Boxes	2152
37.7 Example Using the <i>topology</i> and the <i>cutoff</i> Parameters	2152
37.8 Runtime Performance	2154
37.9 Example Using a Custom Box Implementation	2155

37.10	Example for Point Proximity Search with a Custom Traits Class	2157
37.11	Design and Implementation History	2158

Part I

General Introduction

Chapter 1

General Introduction

CGAL, the *Computational Geometry Algorithms Library*, is written in C++ and consists of several parts.

The first part is about the kernels, which consist of constant-size non-modifiable geometric primitive objects and operations on these objects. The objects are represented both as stand-alone classes that are parameterized by a representation class, which specifies the underlying number types used for calculations and as members of the kernel classes, which allows for more flexibility and adaptability of the kernel. CGAL has several kernels, for 2D and 3D, for arbitrary dimensional objects, and for 2D curved objects.

The following parts present a collection of basic geometric data structures and algorithms, which are parameterized by traits classes that define the interface between the data structure or algorithm and the primitives they use. In many cases, the kernel classes provided in CGAL can be used as traits classes for these data structures and algorithms. The collection of basic geometric algorithms and data structures currently includes polygons, half-edge data structures, polyhedral surfaces, arrangements of curves, triangulations in 2D and 3D, surface mesh generators, subdivision and parametrisation of surface meshes, Voronoi diagrams of points, disks and segments, Boolean operations on polygons and polyhedra, convex hulls, alpha shapes, optimisation algorithms, dynamic point sets for geometric queries, range and segment trees, and kinetic data structures.

The last part of the library consists of non-geometric support facilities, such as support for number types, STL extensions for CGAL, handles, circulators, protected access to internal representations, geometric object generators, timers, I/O stream operators and other stream support including PostScript, colors, windows, and visualization tools Geomview and a Qt widget for 2D CGAL objects.

Additional documents accompanying the CGAL distribution are the ‘Installation Guide’ and ‘The Use of STL and STL Extensions in CGAL’, which gives a manual style introduction to STL constructs such as iterators and containers, as well an extension, called circulator, used in many places in CGAL. We also recommend the standard text book by Austern [Aus98] for the STL and its notion of *concepts* and *models*.

Other resources for CGAL are the tutorials at <http://www.cgal.org/Tutorials/> and the user support page at www.cgal.org.

1.1 License Issues

CGAL is Open Source software, and consists of different parts covered by different licenses. In this section we explain the essence of the different licenses, as well as the rationale why we have chosen them.

The fact that CGAL is Open Source software does not mean that users are free to do whatever they want with the software. Using the software means to accept the license, which has the status of a contract between the user and the owner of the CGAL software. A more detailed description of the license terms is available in the CGAL software tarball.

1.1.1 QPL

The QPL is an Open Source license that obliges you to distribute your software based on QPLed CGAL data structures. The rationale behind this is that we can claim access to your software. The license further obliges you to put your software under an Open Source license as well. The rationale behind is that we can distribute your software, even if this is not your intention. Finally, the QPL requires that, if you modify CGAL, you distribute the modifications in the form of patches and you distribute the sources of your changes as well.

The exact license terms as well as an annotated version of the license can be found at the Trolltech web site: <http://www.trolltech.com/products/qt/licenses/licensing/qpl> and <http://www.trolltech.com/products/qt/licenses/licensing/qpl-annotated>

1.1.2 LGPL

The LGPL is an Open Source license that obliges you to distribute modifications you make on CGAL software accessible to the users. There is no obligation to make the source code of software you build on top of LGPLed CGAL data structures available.

Currently the linear kernel, the support library, the halfedge data structure, the kinetic data structures, and the mesh subdivision framework are distributed under the LGPL. The rationale behind is that we want to promote them as defacto standards.

The exact license terms can be found at the Free Software Foundation web site: <http://www.gnu.org/copyleft/lesser.html>.

1.1.3 Commercial Licenses

Users who cannot comply to the Open Source license terms can buy individual data structures under various commercial licenses from GeometryFactory: <http://www.geometryfactory.com>.

1.1.4 License Compatibility

The General Public License (GPL) has a viral effect which makes it incompatible with the QPL. For more information, please refer to the paragraph about the QPL on the licenses web page of the Free Software Foundation (FSF): http://www.fsf.org/licenses/licenses/index_html. It is therefore not possible to build a program including GPL code and some QPL parts of CGAL. In this case, if you are the copyright owner of the GPL code, you can amend the license by adding an exception allowing the use of CGAL with it (see again the FSF web page).

1.2 Third Party Software

In this section we list the software

1.2.1 Standard Template Library

CGAL heavily uses the STL, and in particular adopted many of its design ideas. The STL comes with the compiler, but it is possible to use the compiler together with an alternative STL implementation.

1.2.2 Boost

Boost is a collection of libraries. CGAL needs some of them, that is it is mandatory. If Boost is not already on your system, e.g., on Windows, you can download it from <http://www.boost.org>.

1.2.3 GMP

A library for multi precision integers and rational numbers. CGAL offers adapters for these number types. The usage of the GMP library is optional. If it is not already on your system, e.g., on Windows, you can download it from www.swox.com/gmp or from the Download section of <http://www.cgal.org>.

1.2.4 MPFR

A library for multi precision floating point numbers. The usage of the MPFR library is optional, and you must install it when you use GMP. You can download MPFR from <http://www.mpfr.org> or from the Download section of <http://www.cgal.org>.

1.2.5 Leda

A library of efficient data structures and algorithms. CGAL offers adapters to the LEDA number types. The usage is optional. It is only available commercially from <http://www.algorithmic-solutions.com>.

1.2.6 Taucs

A library of sparse linear solvers. It can be used by the *Surface_mesh_parameterization* package in order to speed up the algorithm. You can download the official release from <http://www.tau.ac.il/~stoledo/taucs/> or download a version customized by CGAL team from the Download section of <http://www.cgal.org>.

1.2.7 OpenNL

OpenNL (Open Numerical Library) is a library to easily construct and solve sparse linear systems. It is the default solver of the *Surface_mesh_parameterization* package.

The author is Bruno Lévy. OpenNL main page is <http://www.loria.fr/~levy/software/>.

CGAL includes a version of OpenNL in C++, made especially for CGAL by Bruno Lévy.

1.2.8 zlib

A data compression library. It is used in the examples of the *Surface_mesher* package. If it is not already on your system, e.g., on Windows, you can download it from <http://www.gzip.org/zlib>.

1.2.9 Qt

A GUI library. The usage of Qt is optional, but note that it is used for all 2D demos.

As Qt is the layer underneath KDE, Qt is installed on many Linux systems. Otherwise you can download it from <http://www.trolltech.com>.

1.2.10 Coin

An implementation of Open Inventor. It is used in the demo of the *Kinetic_data_structures* package. You can download it from <http://www.sim.no>.

1.3 Advanced

In this manual you will encounter sections marked as follows.

— *advanced* —

Some functionality is considered more advanced. Such functionality is described in sections such as this one that are bounded by horizontal brackets.

— *advanced* —

1.4 Namespace CGAL

All names introduced by CGAL, especially those documented in these manuals, are in a namespace called *CGAL*, which is in global scope. A user can either qualify names from CGAL by adding *CGAL::*, e.g., *CGAL::Point_2* < *CGAL::Homogeneous* < *int* > >, make a single name from CGAL visible in a scope via a *using* statement, e.g., *using CGAL::Cartesian*;, and then use this name unqualified in this scope, or even make all names from namespace *CGAL* visible in a scope with *using namespace CGAL*;. The latter, however, is likely to give raise to name conflicts and is therefore not recommended.

1.5 Inclusion Order of Header Files

Not all compilers fully support standard header names. CGAL provides workarounds for these problems in *CGAL/basic.h*. Consequently, as a golden rule, you should always include *CGAL/basic.h* first in your programs (or *CGAL/Cartesian.h*, or *CGAL/Homogeneous.h*, since they include *CGAL/basic.h* first).

1.6 Compile-time Flags to Control Inlining

Making functions inlined can, at times, improve the efficiency of your code. However this is not always the case and it can differ for a single function depending on the application in which it is used. Thus CGAL defines a set of compile-time macros that can be used to control whether certain functions are designated as inlined functions or not. The following table lists the macros and their default values, which are set in one of the CGAL include files.

macro name	default
<i>CGAL_KERNEL_INLINE</i>	inline
<i>CGAL_KERNEL_MEDIUM_INLINE</i>	
<i>CGAL_KERNEL_LARGE_INLINE</i>	
<i>CGAL_MEDIUM_INLINE</i>	inline
<i>CGAL_LARGE_INLINE</i>	
<i>CGAL_HUGE_INLINE</i>	

If you wish to change the value of one or more of these macros, you can simply give it a new value when compiling. For example, to make functions that use the macro *CGAL_KERNEL_MEDIUM_INLINE* inline functions, you should set the value of this macro to `inline` instead of the default blank.

1.7 Checks

Much of the CGAL code contains checks. For example, all checks used in the kernel code are prefixed by *CGAL_KERNEL*. Other packages have their own prefixes, as documented in the corresponding chapters. Some are there to check if the kernel behaves correctly, others are there to check if the user calls kernel routines in an acceptable manner.

There are four types of checks. The first three are errors and lead to a halt of the program if they fail. The last only leads to a warning.

Preconditions check if the caller of a routine has called it in a proper fashion. If such a check fails it is the responsibility of the caller (usually the user of the library).

Postconditions check if a routine does what it promises to do. If such a check fails it is the fault of this routine, so of the library.

Assertions are other checks that do not fit in the above two categories.

Warnings are checks for which it is not so severe if they fail.

By default, all of these checks are performed. It is however possible to turn them off through the use of compile time switches. For example, for the checks in the kernel code, these switches are the following: *CGAL_KERNEL_NO_PRECONDITIONS*, *CGAL_KERNEL_NO_POSTCONDITIONS*, *CGAL_KERNEL_*

NO_ASSERTIONS and *CGAL_KERNEL_NO_WARNINGS*. So, in order to compile the file `foo.C` with the post-condition checks off, you can do:

```
CC -DCGAL_KERNEL_NO_POSTCONDITIONS foo.C
```

This is also preferably done by modifying your makefile by adding *-DCGAL_KERNEL_NO_POSTCONDITIONS* to the *CXXFLAGS* variable.

The name *KERNEL* in the macro name can be replaced by a package specific name in order to control assertions done in a given package. This name is given in the documentation of the corresponding package, in case it exists.

Note that global macros can also be used to control the behavior over the whole CGAL library:

- *CGAL_NO_PRECONDITIONS*,
- *CGAL_NO_POSTCONDITIONS*,
- *CGAL_NO_ASSERTIONS* and
- *CGAL_NO_WARNINGS*.

Moreover, the standard macro *NDEBUG*, which controls the behavior of the *std::assert* function, also affects all checks in CGAL. This way, adding *-DNDEBUG* to your compilation flags removes absolutely all checks, including standard ones using *std::assert*. This is the default recommended setup for performing timing benchmarks for example.

Not all checks are on by default. All four types of checks can be marked as expensive or exactness checks (or both). These checks need to be turned on explicitly by supplying one or both of the compile time switches *CGAL_KERNEL_CHECK_EXPENSIVE* and *CGAL_KERNEL_CHECK_EXACTNESS*.

Expensive checks are, as the word says, checks that take a considerable time to compute. Considerable is an imprecise phrase. Checks that add less than 10 percent to the execution time of the routine they are in are not expensive. Checks that can double the execution time are. Somewhere in between lies the border line. Checks that increase the asymptotic running time of an algorithm are always considered expensive. Exactness checks are checks that rely on exact arithmetic. For example, if the intersection of two lines is computed, the postcondition of this routine may state that the intersection point lies on both lines. However, if the computation is done with doubles as number type, this may not be the case, due to round off errors. So, exactness checks should only be turned on if the computation is done with some exact number type.

1.7.1 Altering the Failure Behaviour

As stated above, if a postcondition, precondition or assertion is violated, the program will abort (stop and produce a core dump). This behaviour can be changed by means of the following function.

```
#include <CGAL/assertions.h>
```

```
Failure_behaviour set_error_behaviour( Failure_behaviour eb)
```

The parameter should have one of the following values.

```
enum Failure_behaviour { ABORT, EXIT, EXIT_WITH_SUCCESS, CONTINUE};
```

The first value is the default. If the *EXIT* value is set, the program will stop and return a value indicating failure, but not dump the core. The last value tells the checks to go on after diagnosing the error.

————— *advanced* —————

If the *EXIT_WITH_SUCCESS* value is set, the program will stop and return a value corresponding to successful execution and not dump the core.

————— *advanced* —————

The value that is returned by *set_error_behaviour* is the value that was in use before.

For warnings there is a separate routine, which works in the same way. The only difference is that for warnings the default value is *CONTINUE*.

Failure_behaviour set_warning_behaviour(Failure_behaviour eb)

1.7.2 Control at a Finer Granularity

The compile time flags as described up to now all operate on the whole library. Sometimes you may want to have a finer control. CGAL offers the possibility to turn checks on and off with a bit finer granularity, namely the module in which the routines are defined. The name of the module is to be appended directly after the CGAL prefix. So, the flag *CGAL_KERNEL_NO_ASSERTIONS* switches off assertions in the kernel only, the flag *CGAL_CH_CHECK_EXPENSIVE* turns on expensive checks in the convex hull module. The name of a particular module is documented with that module.

————— *advanced* —————

1.7.3 Customising how Errors are Reported

Normally, error messages are written to the standard error output. It is possible to do something different with them. To that end you can register your own handler. This function should be declared as follows.

```
void          my_failure_function(
                const char *type,
                const char *expression,
                const char *file,
                int line,
                const char *explanation)
```

Your failure function will be called with the following parameters. *type* is a string that contains one of the words precondition, postcondition, assertion or warning. The parameter *expression* contains the expression that was violated. *file* and *line* contain the place where the check was made. The *explanation* parameter contains an explanation of what was checked. It can be *NULL*, in which case the *expression* is thought to be descriptive enough.

There are several things that you can do with your own handler. You can display a diagnostic message in a different way, for instance in a pop up window or to a log file (or a combination). You can also implement a different policy on what to do after an error. For instance, you can throw an exception or ask the user in a dialogue whether to abort or to continue. If you do this, it is best to set the error behaviour to *CONTINUE*, so that it does not interfere with your policy.

You can register two handlers, one for warnings and one for errors. Of course, you can use the same function for both if you want. When you set a handler, the previous handler is returned, so you can restore it if you want.

```

#include <CGAL/assertions.h>
Failure_function      set_error_handler( Failure_function handler)
Failure_function      set_warning_handler( Failure_function handler)

```

Example

```

#include <CGAL/assertions.h>

void my_failure_handler(
    const char *type,
    const char *expr,
    const char* file,
    int line,
    const char* msg)
{
    /* report the error in some way. */
}

void foo()
{
    CGAL::Failure_function prev;
    prev = CGAL::set_error_handler(my_failure_handler);
    /* call some routines. */
    CGAL::set_error_handler(prev);
}

```

Part II

Kernels

Chapter 2

2D and 3D Kernel

Hervé Brönnimann, Andreas Fabri, Geert-Jan Giezeman, Susan Hert, Michael Hoffmann, Lutz Kettner, Sylvain Pion, and Stefan Schirra

2.1 Introduction

CGAL, the *Computational Geometry Algorithms Library*, is written in C++ and consists of three major parts. The first part is the kernel, which consists of constant-size non-modifiable geometric primitive objects and operations on these objects. The objects are represented both as stand-alone classes that are parameterized by a representation class, which specifies the underlying number types used for calculations and as members of the kernel classes, which allows for more flexibility and adaptability of the kernel. The second part is a collection of basic geometric data structures and algorithms, which are parameterized by traits classes that define the interface between the data structure or algorithm and the primitives they use. In many cases, the kernel classes provided in CGAL can be used as traits classes for these data structures and algorithms. The third part of the library consists of non-geometric support facilities, such as circulators, random sources, I/O support for debugging and for interfacing CGAL to various visualization tools.

This part of the reference manual covers the kernel. The kernel contains objects of constant size, such as point, vector, direction, line, ray, segment, triangle, iso-oriented rectangle and tetrahedron. With each type comes a set of functions which can be applied to an object of this type. You will typically find access functions (e.g. to the coordinates of a point), tests of the position of a point relative to the object, a function returning the bounding box, the length, or the area of an object, and so on. The CGAL kernel further contains basic operations such as affine transformations, detection and computation of intersections, and distance computations.

2.1.1 Robustness

The correctness proof of nearly all geometric algorithms presented in theory papers assumes exact computation with real numbers. This leads to a fundamental problem with the implementation of geometric algorithms. Naively, often the exact real arithmetic is replaced by inexact floating-point arithmetic in the implementation. This often leads to acceptable results for many input data. However, even for the implementation of the simplest geometric algorithms this simplification occasionally does not work. Rounding errors introduced by an inaccurate arithmetic may lead to inconsistent decisions, causing unexpected failures for some correct input data. There are many approaches to this problem, one of them is to compute exactly (compute so accurate that all decisions made by the algorithm are exact) which is possible in many cases but more expensive than standard floating-point arithmetic. C. M. Hoffmann [[Hof89a](#), [Hof89b](#)] illustrates some of the problems arising in the implementation of geometric algorithms and discusses some approaches to solve them. A more recent overview

is given in [Sch00]. The exact computation paradigm is discussed by Yap and Dubé [YD95] and Yap [Yap97].

In CGAL you can choose the underlying number types and arithmetic. You can use different types of arithmetic simultaneously and the choice can be easily changed, e.g. for testing. So you can choose between implementations with fast but occasionally inexact arithmetic and implementations guaranteeing exact computation and exact results. Of course you have to pay for the exactness in terms of execution time and storage space. See the section on number types in the Support Library for more details on number types and their capabilities and performance.

2.2 Kernel Representations

Our object of study is the d -dimensional affine Euclidean space. Here we are mainly concerned with cases $d = 2$ and $d = 3$. Objects in that space are sets of points. A common way to represent the points is the use of Cartesian coordinates, which assumes a reference frame (an origin and d orthogonal axes). In that framework, a point is represented by a d -tuple $(c_0, c_1, \dots, c_{d-1})$, and so are vectors in the underlying linear space. Each point is represented uniquely by such Cartesian coordinates. Another way to represent points is by homogeneous coordinates. In that framework, a point is represented by a $(d + 1)$ -tuple (h_0, h_1, \dots, h_d) . Via the formulae $c_i = h_i/h_d$, the corresponding point with Cartesian coordinates $(c_0, c_1, \dots, c_{d-1})$ can be computed. Note that homogeneous coordinates are not unique. For $\lambda \neq 0$, the tuples (h_0, h_1, \dots, h_d) and $(\lambda \cdot h_0, \lambda \cdot h_1, \dots, \lambda \cdot h_d)$ represent the same point. For a point with Cartesian coordinates $(c_0, c_1, \dots, c_{d-1})$ a possible homogeneous representation is $(c_0, c_1, \dots, c_{d-1}, 1)$. Homogeneous coordinates in fact allow to represent objects in a more general space, the projective space \mathbb{P}_d . In CGAL, we do not compute in projective geometry. Rather, we use homogeneous coordinates to avoid division operations, since the additional coordinate can serve as a common denominator.

2.2.1 Genericity through Parameterization

Almost all the kernel objects (and the corresponding functions) are templates with a parameter that allows the user to choose the representation of the kernel objects. A type that is used as an argument for this parameter must fulfill certain requirements on syntax and semantics. The list of requirements defines an abstract kernel concept. For all kernel objects types, the types `CGAL::Type<Kernel>` and `Kernel::Type` are identical.

CGAL offers four families of concrete models for the concept Kernel, two based on the Cartesian representation of points and two based on the homogeneous representation of points. The interface of the kernel objects is designed such that it works well with both Cartesian and homogeneous representation. For example, points in 2D have a constructor with three arguments as well (the three homogeneous coordinates of the point). The common interfaces parameterized with a kernel class allow one to develop code independent of the chosen representation. We said “families” of models, because both families are parameterized too. A user can choose the number type used to represent the coordinates.

For reasons that will become evident later, a kernel class provides two typenames for number types, namely `Kernel::FT` and `Kernel::RT`.¹ The type `Kernel::FT` must fulfill the requirements on what is called a *FieldNumberType* in CGAL. This roughly means that `Kernel::FT` is a type for which operations $+$, $-$, $*$ and $/$ are defined with semantics (approximately) corresponding to those of a field in a mathematical sense. Note that, strictly speaking, the built-in type `int` does not fulfill the requirements on a field type, since *ints* correspond to elements of a ring rather than a field, especially operation $/$ is not the inverse of $*$. The requirements on the type `Kernel::RT` are weaker. This type must fulfill the requirements on what is called a *RingNumberType* in CGAL. This roughly means that `Kernel::RT` is a type for which operations $+$, $-$, $*$ are defined with semantics (approximately) corresponding to those of a ring in a mathematical sense.

¹The double colon `::` is the C++ scope operator.

2.2.2 Cartesian Kernels

With *Cartesian*<*FieldNumberType*> you can choose a Cartesian representation of coordinates. When you choose Cartesian representation you have to declare at the same time the type of the coordinates. A number type used with the *Cartesian* representation class should be a *FieldNumberType* as described above. As mentioned above, the built-in type *int* is not a *FieldNumberType*. However, for some computations with Cartesian representation, no division operation is needed, i.e., a *RingNumberType* is sufficient in this case. With *Cartesian*<*FieldNumberType*>, both *Cartesian*<*FieldNumberType*>::*FT* and *Cartesian*<*FieldNumberType*>::*RT* are mapped to *FieldNumberType*.

Cartesian<*FieldNumberType*> uses reference counting internally to save copying costs. CGAL also provides *Simple_cartesian*<*FieldNumberType*>, a kernel that uses Cartesian representation but no reference counting. Debugging is easier with *Simple_cartesian*<*FieldNumberType*>, since the coordinates are stored within the class and hence direct access to the coordinates is possible. Depending on the algorithm, it can also be slightly more or less efficient than *Cartesian*<*FieldNumberType*>. Again, in *Simple_cartesian*<*FieldNumberType*> both *Simple_cartesian*<*FieldNumberType*>::*FT* and *Simple_cartesian*<*FieldNumberType*>::*RT* are mapped to *FieldNumberType*.

2.2.3 Homogeneous Kernels

Homogeneous coordinates permit to avoid division operations in numerical computations, since the additional coordinate can serve as a common denominator. Avoiding divisions can be useful for exact geometric computation. With *Homogeneous*<*RingNumberType*> you can choose a homogeneous representation for the coordinates of the kernel objects. As for the Cartesian representation, one has to declare the type used to store the coordinates. Since the homogeneous representation does not use divisions, the number type associated with a homogeneous representation class must be a model for the weaker concept *RingNumberType* only. However, some operations provided by this kernel involve divisions, for example computing squared distances or Cartesian coordinates. To keep the requirements on the number type parameter of *Homogeneous* low, the number type *Quotient*<*RingNumberType*> is used for operations that require divisions. This number type can be viewed as an adaptor which turns a *RingNumberType* into a *FieldNumberType*. It maintains numbers as quotients, i.e., a numerator and a denominator. With *Homogeneous*<*RingNumberType*>, *Homogeneous*<*RingNumberType*>::*FT* is equal to *Quotient*<*RingNumberType*>, while *Homogeneous*<*RingNumberType*>::*RT* is equal to *RingNumberType*.

Homogeneous<*RingNumberType*> uses reference counting internally to save copying costs. CGAL also provides *Simple_homogeneous*<*RingNumberType*>, a kernel that uses homogeneous representation but no reference counting. Debugging is easier with *Simple_homogeneous*<*RingNumberType*>, since the coordinates are stored within the class and hence direct access to the coordinates is possible. Depending on the algorithm, it can also be slightly more or less efficient than *Homogeneous*<*RingNumberType*>. Again, in *Simple_homogeneous*<*RingNumberType*> the type *Simple_homogeneous*<*RingNumberType*>::*FT* is equal to *Quotient*<*RingNumberType*> while *Simple_homogeneous*<*RingNumberType*>::*RT* is equal to *RingNumberType*.

2.2.4 Naming conventions

The use of kernel classes not only avoids problems, it also makes all CGAL classes very uniform. They **always** consist of:

1. The *capitalized base name* of the geometric object, such as *Point*, *Segment*, or *Triangle*.
2. An *underscore* followed by the *dimension* of the object, for example *_2*, *_3*, or *_d*.

3. A *kernel class* as parameter, which itself is parameterized with a number type, such as *Cartesian<double>* or *Homogeneous<leda_integer>*.

2.2.5 Kernel as a Traits Class

Algorithms and data structures in the basic library of CGAL are parameterized by a traits class that subsumes the objects on which the algorithm or data structure operates as well as the operations to do so. For most of the algorithms and data structures in the basic library you can use a kernel as a traits class. For some algorithms you even do not have to specify the kernel; it is detected automatically using the types of the geometric objects passed to the algorithm. In some other cases, the algorithms or data structures needs more than is provided by the kernel concept. In these cases, a kernel can not be used as a traits class.

2.2.6 Choosing a Kernel and Predefined Kernels

If you start with integral Cartesian coordinates, many geometric computations will involve integral numerical values only. Especially, this is true for geometric computations that evaluate only predicates, which are tantamount to determinant computations. Examples are triangulation of point sets and convex hull computation. In this case, the Cartesian representation is probably the first choice, even with a ring type. You might use limited precision integer types like *int* or *long*, use *double* to present your integers (they have more bits in their mantissa than an *int* and overflow nicely), or an arbitrary precision integer type like the wrapper *Gmpz* for the GMP integers, *leda_integer*, or *MP_Float*. Note, that unless you use an arbitrary precision ring type, incorrect results might arise due to overflow.

If new points are to be constructed, for example the intersection point of two lines, computation of Cartesian coordinates usually involves divisions. Hence, one needs to use a *FieldNumberType* with Cartesian representation, or alternatively, switch to homogeneous representation. The type *double* is a – though imprecise – model for *FieldNumberType*. You can also put any *RingNumberType* into the *Quotient* adaptor to get a field type which then can be put into *Cartesian*. But using homogeneous representation on the *RingNumberType* is usually the better option. Other valid *FieldNumberTypes* are *leda_rational* and *leda_real*.

If it is crucial for you that the computation is reliable, the right choice is probably a number type that guarantees exact computation. The *Filtered_kernel* provides a way to apply filtering techniques [BBP01] to achieve a kernel with exact and efficient predicates. Still other people will prefer the built-in type *double*, because they need speed and can live with approximate results, or even algorithms that, from time to time, crash or compute incorrect results due to accumulated rounding errors.

Predefined kernels. For the user's convenience, CGAL provides 3 typedefs to generally useful kernels.

- They are all Cartesian kernels.
- They all support constructions of points from *double* Cartesian coordinates.
- All these 3 kernels provide exact geometric predicates.
- They handle geometric constructions differently:
 - *Exact_predicates_exact_constructions_kernel*: provides exact geometric constructions, in addition to exact geometric predicates.

- *Exact_predicates_exact_constructions_kernel_with_sqrt*: same as *Exact_predicates_exact_constructions_kernel*, but the number type it provides (*Exact_predicates_exact_constructions_kernel_with_sqrt::FT*) supports the square root operation exactly².
- *Exact_predicates_inexact_constructions_kernel*: provides exact geometric predicates, but geometric constructions may be inexact due to roundoff errors. It is however enough for most CGAL algorithms, and faster than both *Exact_predicates_exact_constructions_kernel* and *Exact_predicates_exact_constructions_kernel_with_sqrt*.

2.3 Kernel Geometry

2.3.1 Points and Vectors

In CGAL, we strictly distinguish between points, vectors and directions. A *point* is a point in the Euclidean space \mathbb{E}^d , a *vector* is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2 in the vector space \mathbb{R}^d , and a *direction* is a vector where we forget about its length. They are different mathematical concepts. For example, they behave different under affine transformations and an addition of two points is meaningless in affine geometry. By putting them in different classes we not only get cleaner code, but also type checking by the compiler which avoids ambiguous expressions. Hence, it pays twice to make this distinction.

CGAL defines a symbolic constant *ORIGIN* of type *Origin* which denotes the point at the origin. This constant is used in the conversion between points and vectors. Subtracting it from a point p results in the locus vector of p .

```
Point_2< Cartesian<double> > p(1.0, 1.0), q;
Vector_2< Cartesian<double> > v;
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

In order to obtain the point corresponding to a vector v you simply have to add v to *ORIGIN*. If you want to determine the point q in the middle between two points p_1 and p_2 , you can write³

```
q = p_1 + (p_2 - p_1) / 2.0;
```

Note that these constructions do not involve any performance overhead for the conversion with the currently available representation classes.

2.3.2 Kernel Objects

Besides points (*Point_2<Kernel>*, *Point_3<Kernel>*, *Point_d<Kernel>*), vectors (*Vector_2<Kernel>*, *Vector_3<Kernel>*), and directions (*Direction_2<Kernel>*, *Direction_3<Kernel>*), CGAL provides lines, rays, segments, planes, triangles, tetrahedra, iso-rectangles, iso-cuboids, circles and spheres.

Lines (*Line_2<Kernel>*, *Line_3<Kernel>*) in CGAL are oriented. In two-dimensional space, they induce a partition of the plane into a positive side and a negative side. Any two points on a line induce an orientation of this

²Currently it requires having either LEDA or CORE installed

³you might call *midpoint(p_1,p_2)* instead

line. A ray (*Ray_2<Kernel>*, *Ray_3<Kernel>*) is semi-infinite interval on a line, and this line is oriented from the finite endpoint of this interval towards any other point in this interval. A segment (*Segment_2<Kernel>*, *Segment_3<Kernel>*) is a bounded interval on a directed line, and the endpoints are ordered so that they induce the same direction as that of the line.

Planes are affine subspaces of dimension two in \mathbb{E}^3 , passing through three points, or a point and a line, ray, or segment. CGAL provides a correspondence between any plane in the ambient space \mathbb{E}^3 and the embedding of \mathbb{E}^2 in that space. Just like lines, planes are oriented and partition space into a positive side and a negative side. In CGAL, there are no special classes for halfspaces. Halfspaces in 2D and 3D are supposed to be represented by oriented lines and planes, respectively.

Concerning polygons and polyhedra, the kernel provides triangles, iso-oriented rectangles, iso-oriented cuboids and tetrahedra. More complex polygons⁴ and polyhedra or polyhedral surfaces can be obtained from the basic library (*Polygon_2*, *Polyhedron_3*), so they are not part of the kernel. As with any Jordan curves, triangles, iso-oriented rectangles and circles separate the plane into two regions, one bounded and one unbounded.

2.3.3 Orientation and Relative Position

Geometric objects in CGAL have member functions that test the position of a point relative to the object. Full dimensional objects and their boundaries are represented by the same type, e.g. halfspaces and hyperplanes are not distinguished, neither are balls and spheres and discs and circles. Such objects split the ambient space into two full-dimensional parts, a bounded part and an unbounded part (e.g. circles), or two unbounded parts (e.g. hyperplanes). By default these objects are oriented, i.e., one of the resulting parts is called the positive side, the other one is called the negative side. Both of these may be unbounded.

For these objects there is a function *oriented_side()* that determines whether a test point is on the positive side, the negative side, or on the oriented boundary. These function returns a value of type *Oriented_side*.

Those objects that split the space in a bounded and an unbounded part, have a member function *bounded_side()* with return type *Bounded_side*.

If an object is lower dimensional, e.g. a triangle in three-dimensional space or a segment in two-dimensional space, there is only a test whether a point belongs to the object or not. This member function, which takes a point as an argument and returns a boolean value, is called *has_on()*

2.4 Predicates and Constructions

2.4.1 Predicates

Predicates are at the heart of a geometry kernel. They are basic units for the composition of geometric algorithms and encapsulate decisions. Hence their correctness is crucial for the control flow and hence for the correctness of an implementation of a geometric algorithm. CGAL uses the term predicate in a generalized sense. Not only components returning a Boolean value are called predicates but also components returning an enumeration type like a *Comparison_result* or an *Orientation*. We say components, because predicates are implemented both as functions and function objects (provided by a kernel class).

CGAL provides predicates for the orientation of point sets (*orientation*, *leftturn*, *rightturn*, *collinear*, *coplanar*), for comparing points according to some given order, especially for comparing Cartesian coordinates

⁴Any sequence of points can be seen as a (not necessary simple) polygon or polyline. This view is used frequently in the basic library as well.

(e.g. *lexicographically_xy_smaller*), in-circle and in-sphere tests, and predicates to compare distances.

2.4.2 Constructions

Functions and function objects that generate objects that are neither of type *bool* nor enum types are called constructions. Constructions involve computation of new numerical values and may be imprecise due to rounding errors unless a kernel with an exact number type is used.

Affine transformations (*Aff_transformation_2<Kernel>*, *Aff_transformation_3<Kernel>*) allow to generate new object instances under arbitrary affine transformations. These transformations include translations, rotations (in 2D only) and scaling. Most of the geometric objects in a kernel have a member function *transform(Aff_transformation t)* which applies the transformation to the object instance.

CGAL also provides a set of functions that detect or compute the intersection between objects of the 2D kernel, and many objects in the 3D kernel, and functions to calculate their squared distance. Moreover, some member functions of kernel objects are constructions.

So there are routines that compute the square of the Euclidean distance, but no routines that compute the distance itself. Why? First of all, the two values can be derived from each other quite easily (by taking the square root or taking the square). So, supplying only the one and not the other is only a minor inconvenience for the user. Second, often either value can be used. This is for example the case when (squared) distances are compared. Third, the library wants to stimulate the use of the squared distance instead of the distance. The squared distance can be computed in more cases and the computation is cheaper. We do this by not providing the perhaps more natural routine. The problem of a distance routine is that it needs the *sqrt* operation. This has two drawbacks:

- The *sqrt* operation can be costly. Even if it is not very costly for a specific number type and platform, avoiding it is always cheaper.
- There are number types on which no *sqrt* operation is defined, especially integer types and rationals.

2.4.3 Polymorphic Return Values

Some functions can return different types of objects. A typical C++ solution to this problem is to derive all possible return types from a common base class, to return a pointer to this class and to perform a dynamic cast on this pointer. The class *Object* provides an abstraction. An object *obj* of the class *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make_object()*. This encapsulation mechanism requires the use of *assign* or *object_cast* to access the encapsulated class.

Example

In the following example, the object class is used as return value for the intersection computation, as there are possibly different return values.

```
{
    typedef Cartesian<double> K;
    typedef K::Point_2      Point_2;
    typedef K::Segment_2    Segment_2;
```

```

Point_2 point;
Segment_2 segment, segment_1, segment_2;

std::cin >> segment_1 >> segment_2;

Object obj = intersection(segment_1, segment_2);

if (assign(point, obj)) {
    /* do something with point */
} else if ((assign(segment, obj)) {
    /* do something with segment*/
}

/* there was no intersection */
}

```

A more efficient way is to use *object_cast* :

```

{
    typedef Cartesian<double> K;
    typedef K::Point_2      Point_2;
    typedef K::Segment_2     Segment_2;

    Segment_2 segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (const Point_2 *point = object_cast<Point_2>(&obj)) {
        /* do something with *point */
    } else if (const Segment_2 *segment = object_cast<Segment_2>(&obj)) {
        /* do something with *segment*/
    }

    /* there was no intersection */
}

```

The intersection routine itself looks roughly as follows:

```

template < class Kernel >
Object intersection(Segment_2<Kernel> s1, Segment_2<Kernel> s2)
{

    if (/* intersection in a point */ ) {

        Point_2<Kernel> p = ... ;
        return make_object(p);
    }
}

```

```

    } else if (/* intersection in a segment */ ) {

        Segment_2<Kernel> s = ... ;
        return make_object(s);
    }
    return Object();
}

```

2.4.4 Constructive Predicates

For testing where a point p lies with respect to a plane defined by three points q , r and s , one may be tempted to construct the plane $\text{Plane_3}<\text{Kernel}>(q,r,s)$ and use the method $\text{oriented_side}(p)$. This may pay off if many tests with respect to the plane are made. Nevertheless, unless the number type is exact, the constructed plane is only approximated, and round-off errors may lead $\text{oriented_side}(p)$ to return an orientation which is different from the orientation of p , q , r , and s .

In CGAL, we provide predicates in which such geometric decisions are made directly with a reference to the input points p , q , r , s , without an intermediary object like a plane. For the above test, the recommended way to get the result is to use $\text{orientation}(p,q,r,s)$. For exact number types, the situation is different. If several tests are to be made with the same plane, it pays off to construct the plane and to use $\text{oriented_side}(p)$.

2.5 Extensible Kernel

This manual section describe how users can plug user defined geometric classes in existing CGAL kernels. This is best illustrated by an example.

2.5.1 Introduction

CGAL defines the concept of a geometry kernel. Such a kernel provides types, construction objects and generalized predicates. Most implementations of Computational Geometry algorithms and data structures in the basic library of CGAL were done in a way that classes or functions can be parametrized with a geometric traits class.

In most cases this geometric traits class must be a model of the CGAL geometry kernel concept (but there are some exceptions).

2.5.2 An Extensive Example

Assume you have the following point class, where the coordinates are stored in an array of *doubles*, where we have another data member *color*, which shows up in the constructor.

```

class MyPointC2 {

private:
    double vec[2];
    int col;

```

```

public:

    MyPointC2()
        : col(0)
    {
        *vec = 0;
        *(vec+1) = 0;
    }

    MyPointC2(const double x, const double y, int c)
        : col(c)
    {
        *vec = x;
        *(vec+1) = y;
    }

    const double& x() const { return *vec; }

    const double& y() const { return *(vec+1); }

    double & x() { return *vec; }

    double& y() { return *(vec+1); }

    int color() const { return col; }

    int& color() { return col; }

    bool operator==(const MyPointC2 &p) const
    {
        return ( *vec == *(p.vec) )  && ( *(vec+1) == *(p.vec + 1) && ( col == p.col) );
    }

    bool operator!=(const MyPointC2 &p) const
    {
        return !(*this == p);
    }

};

```

As said earlier the class is pretty minimalistic, for example it has no *bbox()* method. One might assume that a basic library algorithm which computes a bounding box (e.g. to compute the bounding box of a polygon), will not compile. Luckily it will, because it does not use of member functions of geometric objects, but it makes use of the functor *Kernel::Construct_bbox_2*.

To make the right thing happen with *MyPointC2* we have to provide the following functor.

```

template <class ConstructBbox_2>
class MyConstruct_bbox_2 : public ConstructBbox_2 {
public:

```

```

CGAL::Bbox_2 operator()(const typename MyPointC2& p) const {
    return CGAL::Bbox_2(p.x(), p.y(), p.x(), p.y());
}
};

```

Things are similar for random access to the Cartesian coordinates of a point. As the coordinates are stored in an array of *doubles* we can use *double** as random access iterator.

```

class MyConstruct_coord_iterator {
public:
    const double* operator()(const MyPointC2& p)
    {
        return &p.x();
    }

    const double* operator()(const MyPointC2& p, int)
    {
        const double* pyptr = &p.y();
        pyptr++;
        return pyptr;
    }
};

```

The last functor we have to provide is the one which constructs points. That is you are not forced to add the constructor with the *Origin* as parameter to your class, nor the constructor with homogeneous coordinates. The functor is a kind of glue layer between the CGAL algorithms and your class.

```

template <typename K>
class MyConstruct_point_2
{
    typedef typename K::RT      RT;
    typedef typename K::Point_2 Point_2;
public:
    typedef Point_2      result_type;
    typedef CGAL::Arity_tag< 1 >  Arity;

    Point_2
    operator()(CGAL::Origin o) const
    { return Point_2(0,0, 0); }

    Point_2
    operator()(const RT& x, const RT& y) const
    { return Point_2(x, y, 0); }

    // We need this one, as such a functor is in the Filtered_kernel
    Point_2
    operator()(const RT& x, const RT& y, const RT& w) const
    {
        if(w != 1){
            return Point_2(x/w, y/w, 0);
        } else {

```

```

return Point_2(x,y, 0);
    }
}
};

```

Now we are ready to put the puzzle together. We won't explain it in detail, but you see that there are *typedefs* to the new point class and the functors. All the other types are inherited.

```

#ifndef MYKERNEL_H
#define MYKERNEL_H

#include <CGAL/Cartesian.h>
#include "MyPointC2.h"
#include "MySegmentC2.h"

// K_ is the new kernel, and K_Base is the old kernel
template < typename K_, typename K_Base >
class MyCartesian_base
: public K_Base::template Base<K_>::Type
{
    typedef typename K_Base::template Base<K_>::Type    OldK;
public:
    typedef K_                                            Kernel;
    typedef MyPointC2                                    Point_2;
    typedef MySegmentC2<Kernel>                          Segment_2;
    typedef MyConstruct_point_2<Kernel, OldK>             Construct_point_2;
    typedef const double*                                Cartesian_const_iterator_2;
    typedef MyConstruct_coord_iterator                   Construct_cartesian_const_iterator_2;
    typedef MyConstruct_bbox_2<typename OldK::Construct_bbox_2> Construct_bbox_2;

    Construct_point_2
    construct_point_2_object() const
    { return Construct_point_2(); }

    template < typename Kernel2 >
    struct Base { typedef MyCartesian_base<Kernel2, K_Base>  Type; };
};

template < typename FT_ >
struct MyKernel
: public CGAL::Type_equality_wrapper<
    MyCartesian_base<MyKernel<FT_>, CGAL::Cartesian<FT_> >,
    MyKernel<FT_> >
{};

#endif // MYKERNEL_H

```

Finally, we give an example how this new kernel can be used. Predicates and constructions work with the new point, they can be used to construct segments and triangles with, and data structures from the Basic Library, as the Delaunay triangulation work with them.

The kernel itself can be made robust by plugging it in the *Filtered_kernel*.

```
// file: examples/Kernel_23/MyKernel.C

#include <CGAL/basic.h>
#include <CGAL/Filtered_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/squared_distance_2.h>
#include <cassert>
#include "MyKernel.h"

typedef MyKernel<double> MK;
typedef CGAL::Filtered_kernel_adaptor<MK> K;
typedef CGAL::Delaunay_triangulation_2<K> Delaunay_triangulation_2;

typedef K::Point_2 Point;
typedef K::Segment_2 Segment;
typedef K::Ray_2 Ray;
typedef K::Line_2 Line;
typedef K::Triangle_2 Triangle;
typedef K::Iso_rectangle_2 Iso_rectangle;

const int RED= 1;
const int BLACK=2;

int main()
{
    Point a(0,0), b(1,0, BLACK), c(1,1), d(0,1);
    a.color()=RED;
    b.color()=BLACK;
    d.color()=RED;

    Delaunay_triangulation_2 dt;
    dt.insert(a);

    K::Orientation_2 orientation;
    orientation(a,b,c);

    Point p(1,2), q;
    p.color() = RED;
    q.color() = BLACK;
    std::cout << p << std::endl;

    K::Compute_squared_distance_2 squared_distance;

    std::cout << "squared_distance(a, b) == "
                << squared_distance(a, b) << std::endl;

    Segment s1(p,q), s2(a, c);

    K::Construct_midpoint_2 construct_midpoint_2;
```

```

Point mp = construct_midpoint_2(p,q);

assert(s1.source().color() == RED);

K::Intersect_2 intersection;

CGAL::Object o = intersection(s1, s2);

K::Construct_cartesian_const_iterator_2 construct_it;
K::Cartesian_const_iterator_2 cit = construct_it(a);
assert(*cit == a.x());

cit = construct_it(a,0);

cit--;
assert(*cit == a.y());

Line l1(a,b), l2(p, q);

intersection(l1, l2);

intersection(s1, l1);

Ray r1(d,b), r2(d,c);
intersection(r1, r2);

intersection(r1, l1);

squared_distance(r1, r2);
squared_distance(r1, l2);
squared_distance(r1, s2);

Triangle t1(a,b,c), t2(a,c,d);
intersection(t1, t2);
intersection(t1, l1);

intersection(t1, s1);

intersection(t1, r1);

Iso_rectangle i1(a,c), i2(d,p);
intersection(i1, i2);
intersection(i1, s1);

intersection(i1, r1);
intersection(i1, l1);

t1.orientation();

std::cout << s1.source() << std::endl;

std::cout << t1.bbox() << std::endl;

```

```

std::cout << "done" << std::endl;
return 0;
}

```

2.5.3 Limitations

The point class must have member functions $x()$ and $y()$ (and $z()$ for the 3d point). We will probably introduce function objects that take care of coordinate access.

As we enforce type equality between *MyKernel::Point_2* and *Point_2<MyKernel>*, the constructor with the color as third argument is not available.

2.6 Kernel Related Tools

2.6.1 Introduction

The following manual sections describe various tools that might be useful for various kinds of users of the CGAL kernel. The kernel concept archetype describes a minimal model for the CGAL kernel that can be used for testing CGAL kernel compatibility of geometrical algorithm implementations. It can be useful for all people developing CGAL-style code that uses the CGAL kernel.

2.6.2 Kernel Concept Archetype

Introduction

CGAL defines the concept of a geometry kernel. Such a kernel provides types, construction objects and generalized predicates. Most implementations of CG algorithms and data structures in the basic library of CGAL were done in a way that classes or functions can be parametrized with a geometric traits class.

In most cases this geometric traits class must be a model of the CGAL geometry kernel concept (but there are some exceptions).

The CGAL distribution comes with a number of models (or geometry kernels), for instance the Cartesian kernel (*CGAL::Cartesian*) or the homogeneous kernel (*CGAL::Homogeneous*), that can be used with the packages of the basic library.

But does it mean that packages of the basic library are fully compatible with the CGAL kernel concept if they can be used with these CGAL kernel models? Not necessarily, because such a package might also use member functions or global functions/operators, that are implemented for CGAL kernel types but not for other classes or kernels.

That's why it is important to verify whether the documented requirements of a package are really covered by the implementation. Manual verification is error prone, so there should be something better available in a generic library for this application.

That's why the CGAL kernel concept archetype *CGAL::Kernel_archetype* was developed. It provides all functionality required by the CGAL kernel concept, but nothing more, so it can be seen as a minimal implementation

of a model for the CGAL kernel concept. It can be used for testing successful compilation of packages of the basic library with a minimal model. Deprecated kernel functionality is not supported. All geometrical types (like the 2d/3d point or segment types) of *CGAL::Kernel_archetype* have copy constructors, default constructors and an assignment operator, and nothing else. Comparison operators are by default not supported, but can be switched on by the flag *CGAL_CONCEPT_ARCHETYPE_ALLOW_COMPARISONS*.

The geometrical types of the concept archetype encapsulate no data members, so runtime checks with the archetype are not very useful (*CGAL::Kernel_archetype* is only meant for compilation checks with a minimal model in the testsuites of CGAL packages).

The header file for the concept archetype is *CGAL/Kernel_archetype.h*.

The package supports the two- and three-dimensional part of the CGAL kernel concept. The d-dimensional part is not supported.

Restricting the Interface

Normally packages of the Basic Library or Extension packages use only a small subset of the functionality offered by models of the CGAL kernel concept. In these cases testing with a model that offers only this (used and) documented subset makes sense. *CGAL::Kernel_archetype* normally offers the full functionality (all types, functors and constructions of a CGAL kernel model), but it is possible to restrict the interface.

If you want to do this, you have to define the macro *CGAL_CA_LIMITED_INTERFACE* (before the inclusion of *CGAL/Kernel_archetype.h*) for switching on the interface limitation. Now you have to tell the kernel archetype what types have to be provided by it. For every type you have to define a macro. The name of the macro is *CGAL_CA_NAME_OF_KERNEL_TYPE*, where *NAME_OF_KERNEL_TYPE* is the name of the kernel type (written in capitals) that has to be provided by the kernel archetype for a specific package. Lets have a look at a small example. The kernel archetype has to provide in some test suite a limited interface. The interface has to offer type definitions for *Point_3* and *Plane_3* and the 3d orientation functor type definition *Orientation_3*:

```
// limit interface of the Kernel_archetype
#define CGAL_CA_LIMITED_INTERFACE
#define CGAL_CA_POINT_3
#define CGAL_CA_PLANE_3
#define CGAL_CA_ORIENTATION_3

#include <CGAL/Kernel_archetype.h>
```

Now other kernel functionality is removed from the interface of *CGAL::Kernel_archetype*, so access to these other kernel types will result in a compile-time error. Another option is to use an own archetype class that encapsulates only the needed type definitions and the corresponding member functions. See the following code snippet for a simple example.

```
#include <CGAL/Kernel_archetype.h>

// build an own archetype class ...

// get needed types from the kernel archetype ...
typedef CGAL::Kernel_archetype      KA;
typedef KA::Point_3                  KA_Point_3;
typedef KA::Plane_3                  KA_Plane_3;
typedef KA::Construct_opposite_plane_3 KA_Construct_opposite_plane_3;
```

```
// reuse the types from the kernel archetype in the own archetype class
struct My_archetype {
    typedef KA_Point_3          Point_3;
    typedef KA_Plane_3         Plane_3;
    typedef KA_Construct_opposite_plane_3 Construct_opposite_plane_3;

    Construct_opposite_plane_3
    construct_opposite_plane_3_object()
    { return Construct_opposite_plane_3(); }
};
```

Example Program

The following example shows a program for checking the 2d convex hull algorithm of CGAL with the archetype. You can see the usage of the *CGAL::Kernel_archetype* that replaces a CGAL kernel that is normally used.

test_convex_hull_2.C :

```
#include <CGAL/basic.h>
#include <CGAL/convex_hull_2.h>
#include <CGAL/Kernel_archetype.h>
#include <list>

typedef CGAL::Kernel_archetype K;
typedef K::Point_2 Point_2;

int main()
{
    std::list<Point_2> input;

    Point_2 act;
    input.push_back(act);

    std::list<Point_2> output;

    K traits;

    CGAL::convex_hull_2(input.begin(), input.end(),
                        std::back_inserter(output), traits);
    return 0;
}
```

2.7 Concepts

Kernel

The concept of a *kernel* is defined by a set of requirements on the provision of certain types and access member functions to create objects of these types. The types are function object classes to be used within the algorithms and data structures in the basic library of CGAL. This allows you to use any model of a kernel as a traits class in the CGAL algorithms and data structures, unless they require types beyond those provided by a kernel.

A kernel provides types, construction objects, and generalized predicates. The former replace constructors of the kernel classes and constructive procedures in the kernel. There are also function objects replacing operators, especially for equality testing.

Has Models

<i>CGAL::Cartesian</i> < <i>FieldNumberType</i> >	page 41
<i>CGAL::Homogeneous</i> < <i>RingNumberType</i> >	page 48
<i>CGAL::Simple_cartesian</i> < <i>FieldNumberType</i> >	page 55
<i>CGAL::Simple_homogeneous</i> < <i>RingNumberType</i> >	page 56

Types

<i>Kernel::FT</i>	a model of <i>FieldNumberType</i>
<i>Kernel::RT</i>	a model of <i>RingNumberType</i>

Two-dimensional Kernel

Coordinate Access

<i>Kernel::Cartesian_const_iterator_2</i>	a model of <i>Kernel::CartesianConstIterator_2</i>
-------------------------------------------	----------------------------------------------------

Geometric Objects

<i>Kernel::Point_2</i>	a model of <i>Kernel::Point_2</i>
<i>Kernel::Vector_2</i>	a model of <i>Kernel::Vector_2</i>
<i>Kernel::Direction_2</i>	a model of <i>Kernel::Direction_2</i>
<i>Kernel::Line_2</i>	a model of <i>Kernel::Line_2</i>
<i>Kernel::Ray_2</i>	a model of <i>Kernel::Ray_2</i>
<i>Kernel::Segment_2</i>	a model of <i>Kernel::Segment_2</i>
<i>Kernel::Triangle_2</i>	a model of <i>Kernel::Triangle_2</i>
<i>Kernel::Iso_rectangle_2</i>	a model of <i>Kernel::IsoRectangle_2</i>
<i>Kernel::Circle_2</i>	a model of <i>Kernel::Circle_2</i>
<i>Kernel::Object_2</i>	a model of <i>Kernel::Object_2</i>

Constructions

<i>Kernel:: Construct_point_2</i>	a model of <i>Kernel::ConstructPoint_2</i>
<i>Kernel:: Construct_vector_2</i>	a model of <i>Kernel::ConstructVector_2</i>
<i>Kernel:: Construct_direction_2</i>	a model of <i>Kernel::ConstructDirection_2</i>
<i>Kernel:: Construct_segment_2</i>	a model of <i>Kernel::ConstructSegment_2</i>
<i>Kernel:: Construct_line_2</i>	a model of <i>Kernel::ConstructLine_2</i>
<i>Kernel:: Construct_ray_2</i>	a model of <i>Kernel::ConstructRay_2</i>
<i>Kernel:: Construct_circle_2</i>	a model of <i>Kernel::ConstructCircle_2</i>
<i>Kernel:: Construct_triangle_2</i>	a model of <i>Kernel::ConstructTriangle_2</i>
<i>Kernel:: Construct_iso_rectangle_2</i>	a model of <i>Kernel::ConstructIsoRectangle_2</i>
<i>Kernel:: Construct_object_2</i>	a model of <i>Kernel::ConstructObject_2</i>
<i>Kernel:: Construct_scaled_vector_2</i>	a model of <i>Kernel::ConstructScaledVector_2</i>
<i>Kernel:: Construct_translated_point_2</i>	a model of <i>Kernel::ConstructTranslatedPoint_2</i>
<i>Kernel:: Construct_point_on_2</i>	a model of <i>Kernel::ConstructPointOn_2</i>
<i>Kernel:: Construct_projected_point_2</i>	a model of <i>Kernel::ConstructProjectedPoint_2</i>
<i>Kernel:: Construct_projected_xy_point_2</i>	a model of <i>Kernel::ConstructProjectedXYPoint_2</i>
<i>Kernel:: Construct_cartesian_const_iterator_2</i>	a model of <i>Kernel::ConstructCartesianConstIterator_2</i>
<i>Kernel:: Construct_vertex_2</i>	a model of <i>Kernel::ConstructVertex_2</i>
<i>Kernel:: Construct_bbox_2</i>	a model of <i>Kernel::ConstructBbox_2</i>
<i>Kernel:: Construct_perpendicular_vector_2</i>	a model of <i>Kernel::ConstructPerpendicularVector_2</i>
<i>Kernel:: Construct_perpendicular_direction_2</i>	a model of <i>Kernel::ConstructPerpendicularDirection_2</i>
<i>Kernel:: Construct_perpendicular_line_2</i>	a model of <i>Kernel::ConstructPerpendicularLine_2</i>
<i>Kernel:: Construct_max_vertex_2</i>	a model of <i>Kernel::ConstructMaxVertex_2</i>
<i>Kernel:: Construct_midpoint_2</i>	a model of <i>Kernel::ConstructMidpoint_2</i>
<i>Kernel:: Construct_min_vertex_2</i>	a model of <i>Kernel::ConstructMinVertex_2</i>
<i>Kernel:: Construct_center_2</i>	a model of <i>Kernel::ConstructCenter_2</i>
<i>Kernel:: Construct_centroid_2</i>	a model of <i>Kernel::ConstructCentroid_2</i>
<i>Kernel:: Construct_circumcenter_2</i>	a model of <i>Kernel::ConstructCircumcenter_2</i>
<i>Kernel:: Construct_bisector_2</i>	a model of <i>Kernel::ConstructBisector_2</i>
<i>Kernel:: Construct_opposite_direction_2</i>	a model of <i>Kernel::ConstructOppositeDirection_2</i>
<i>Kernel:: Construct_opposite_segment_2</i>	a model of <i>Kernel::ConstructOppositeSegment_2</i>
<i>Kernel:: Construct_opposite_ray_2</i>	a model of <i>Kernel::ConstructOppositeRay_2</i>
<i>Kernel:: Construct_opposite_line_2</i>	a model of <i>Kernel::ConstructOppositeLine_2</i>
<i>Kernel:: Construct_opposite_triangle_2</i>	a model of <i>Kernel::ConstructOppositeTriangle_2</i>
<i>Kernel:: Construct_opposite_circle_2</i>	a model of <i>Kernel::ConstructOppositeCircle_2</i>
<i>Kernel:: Construct_opposite_vector_2</i>	a model of <i>Kernel::ConstructOppositeVector_2</i>

If the result type is not determined, there is no *Construct_* prefix:

<i>Kernel:: Intersect_2</i>	a model of <i>Kernel::Intersect_2</i>
<i>Kernel:: Assign_2</i>	a model of <i>Kernel::Assign_2</i>

If the result type is a number type, the prefix is *Compute_*:

<i>Kernel:: Compute_squared_distance_2</i>	a model of <i>Kernel::ComputeSquaredDistance_2</i>
<i>Kernel:: Compute_squared_length_2</i>	a model of <i>Kernel::ComputeSquaredLength_2</i>
<i>Kernel:: Compute_squared_radius_2</i>	a model of <i>Kernel::ComputeSquaredRadius_2</i>
<i>Kernel:: Compute_area_2</i>	a model of <i>Kernel::ComputeArea_2</i>

Generalized Predicates

<i>Kernel:: Angle_2</i>	a model of <i>Kernel::Angle_2</i>
-------------------------	-----------------------------------

<i>Kernel:: Equal_2</i>	a model of <i>Kernel::Equal_2</i>
<i>Kernel:: Equal_x_2</i>	a model of <i>Kernel::EqualX_2</i>
<i>Kernel:: Equal_y_2</i>	a model of <i>Kernel::EqualY_2</i>
<i>Kernel:: Less_x_2</i>	a model of <i>Kernel::LessX_2</i>
<i>Kernel:: Less_y_2</i>	a model of <i>Kernel::LessY_2</i>
<i>Kernel:: Less_xy_2</i>	a model of <i>Kernel::LessXY_2</i>
<i>Kernel:: Less_yx_2</i>	a model of <i>Kernel::LessYX_2</i>
<i>Kernel:: Compare_x_2</i>	a model of <i>Kernel::CompareX_2</i>
<i>Kernel:: Compare_x_at_y_2</i>	a model of <i>Kernel::CompareXAtY_2</i>
<i>Kernel:: Compare_y_2</i>	a model of <i>Kernel::CompareY_2</i>
<i>Kernel:: Compare_xy_2</i>	a model of <i>Kernel::CompareXY_2</i>
<i>Kernel:: Compare_y_at_x_2</i>	a model of <i>Kernel::CompareYAtX_2</i>
<i>Kernel:: Compare_distance_2</i>	a model of <i>Kernel::CompareDistance_2</i>
<i>Kernel:: Compare_angle_with_x_axis_2</i>	a model of <i>Kernel::CompareAngleWithXAxis_2</i>
<i>Kernel:: Compare_slope_2</i>	a model of <i>Kernel::CompareSlope_2</i>
<i>Kernel:: Less_distance_to_point_2</i>	a model of <i>Kernel::LessDistanceToPoint_2</i>
<i>Kernel:: Less_signed_distance_to_line_2</i>	a model of <i>Kernel::LessSignedDistanceToLine_2</i>
<i>Kernel:: Less_rotate_ccw_2</i>	a model of <i>Kernel::LessRotateCCW_2</i>
<i>Kernel:: Left_turn_2</i>	a model of <i>Kernel::LeftTurn_2</i>
<i>Kernel:: Collinear_2</i>	a model of <i>Kernel::Collinear_2</i>
<i>Kernel:: Orientation_2</i>	a model of <i>Kernel::Orientation_2</i>
<i>Kernel:: Side_of_oriented_circle_2</i>	a model of <i>Kernel::SideOfOrientedCircle_2</i>
<i>Kernel:: Side_of_bounded_circle_2</i>	a model of <i>Kernel::SideOfBoundedCircle_2</i>
<i>Kernel:: Is_horizontal_2</i>	a model of <i>Kernel::IsHorizontal_2</i>
<i>Kernel:: Is_vertical_2</i>	a model of <i>Kernel::IsVertical_2</i>
<i>Kernel:: Is_degenerate_2</i>	a model of <i>Kernel::IsDegenerate_2</i>
<i>Kernel:: Has_on_2</i>	a model of <i>Kernel::HasOn_2</i>
<i>Kernel:: Collinear_has_on_2</i>	a model of <i>Kernel::CollinearHasOn_2</i>
<i>Kernel:: Has_on_bounded_side_2</i>	a model of <i>Kernel::HasOnBoundedSide_2</i>
<i>Kernel:: Has_on_unbounded_side_2</i>	a model of <i>Kernel::HasOnUnboundedSide_2</i>
<i>Kernel:: Has_on_boundary_2</i>	a model of <i>Kernel::HasOnBoundary_2</i>
<i>Kernel:: Has_on_positive_side_2</i>	a model of <i>Kernel::HasOnPositiveSide_2</i>
<i>Kernel:: Has_on_negative_side_2</i>	a model of <i>Kernel::HasOnNegativeSide_2</i>
<i>Kernel:: Oriented_side_2</i>	a model of <i>Kernel::OrientedSide_2</i>
<i>Kernel:: Bounded_side_2</i>	a model of <i>Kernel::BoundedSide_2</i>
<i>Kernel:: Are_parallel_2</i>	a model of <i>Kernel::AreParallel_2</i>
<i>Kernel:: Are_ordered_along_line_2</i>	a model of <i>Kernel::AreOrderedAlongLine_2</i>
<i>Kernel:: Are_strictly_ordered_along_line_2</i>	a model of <i>Kernel::AreStrictlyOrderedAlongLine_2</i>
<i>Kernel:: Collinear_are_ordered_along_line_2</i>	a model of <i>Kernel::CollinearAreOrderedAlongLine_2</i>
<i>Kernel:: Collinear_are_strictly_ordered_along_line_2</i>	a model of <i>Kernel::CollinearAreStrictlyOrderedAlongLine_2</i>
<i>Kernel:: Counterclockwise_in_between_2</i>	a model of <i>Kernel::CounterclockwiseInBetween_2</i>
<i>Kernel:: Do_intersect_2</i>	a model of <i>Kernel::DoIntersect_2</i>

Three-dimensional Kernel

Coordinate Access

<i>Kernel:: Cartesian_const_iterator_3</i>	a model of <i>Kernel::CartesianConstIterator_3</i>
--------------------------------------------	----------------------------------------------------

Geometric Objects

<i>Kernel:: Point_3</i>	a model of <i>Kernel::Point_3</i>
<i>Kernel:: Vector_3</i>	a model of <i>Kernel::Vector_3</i>
<i>Kernel:: Direction_3</i>	a model of <i>Kernel::Direction_3</i>
<i>Kernel:: Iso_cuboid_3</i>	a model of <i>Kernel::IsoCuboid_3</i>
<i>Kernel:: Line_3</i>	a model of <i>Kernel::Line_3</i>
<i>Kernel:: Ray_3</i>	a model of <i>Kernel::Ray_3</i>
<i>Kernel:: Sphere_3</i>	a model of <i>Kernel::Sphere_3</i>
<i>Kernel:: Segment_3</i>	a model of <i>Kernel::Segment_3</i>
<i>Kernel:: Plane_3</i>	a model of <i>Kernel::Plane_3</i>
<i>Kernel:: Triangle_3</i>	a model of <i>Kernel::Triangle_3</i>
<i>Kernel:: Tetrahedron_3</i>	a model of <i>Kernel::Tetrahedron_3</i>
<i>Kernel:: Object_3</i>	a model of <i>Kernel::Object_3</i>

Constructions

<i>Kernel:: Construct_point_3</i>	a model of <i>Kernel::ConstructPoint_3</i>
<i>Kernel:: Construct_vector_3</i>	a model of <i>Kernel::ConstructVector_3</i>
<i>Kernel:: Construct_direction_3</i>	a model of <i>Kernel::ConstructDirection_3</i>
<i>Kernel:: Construct_plane_3</i>	a model of <i>Kernel::ConstructPlane_3</i>
<i>Kernel:: Construct_iso_cuboid_3</i>	a model of <i>Kernel::ConstructIsoCuboid_3</i>
<i>Kernel:: Construct_line_3</i>	a model of <i>Kernel::ConstructLine_3</i>
<i>Kernel:: Construct_ray_3</i>	a model of <i>Kernel::ConstructRay_3</i>
<i>Kernel:: Construct_sphere_3</i>	a model of <i>Kernel::ConstructSphere_3</i>
<i>Kernel:: Construct_segment_3</i>	a model of <i>Kernel::ConstructSegment_3</i>
<i>Kernel:: Construct_triangle_3</i>	a model of <i>Kernel::ConstructTriangle_3</i>
<i>Kernel:: Construct_tetrahedron_3</i>	a model of <i>Kernel::ConstructTetrahedron_3</i>

d-dimensional Kernel

Coordinate Access

<i>Kernel:: Cartesian_const_iterator_d</i>	a model of <i>Kernel::CartesianConstIterator_d</i>
--------------------------------------------	----------------------------------------------------

Geometric Objects

<i>Kernel:: Point_d</i>	a model of <i>Kernel::Point_d</i>
-------------------------	-----------------------------------

Constructions

<i>Kernel:: Construct_Point_d</i>	a model of <i>Kernel::ConstructPoint_d</i>
-----------------------------------	--------------------------------------------

Operations

For each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *Kernel::Construct_vector_2* the following member function must exist:

<i>Kernel::Construct_vector_2</i>	<i>kernel.construct_vector_2_object()</i>

2.8 Kernel Classes and Operations

CGAL::Cartesian<FieldNumberType>

```
#include <CGAL/Cartesian.h>
```

Definition

A model for *Kernel* that uses Cartesian coordinates to represent the geometric objects. In order for *Cartesian*<*FieldNumberType*> to model Euclidean geometry in E^2 and/or E^3 , for some mathematical field E (e.g., the rationals \mathbb{Q} or the reals \mathbb{R}), the template parameter *FieldNumberType* must model the mathematical field E . That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

Kernel page [35](#)

Types

```
typedef FieldNumberType    FT;
typedef FieldNumberType    RT;
```

Implementation

All geometric objects in *Cartesian*<*FieldNumberType*> are reference counted.

CGAL::Simple_homogeneous<*RingNumberType*> page [56](#)

CGAL::Cartesian_converter<K1, K2, NTConverter>

Definition

Cartesian_converter<*K1*, *K2*, *NTConverter*> converts objects from the kernel traits *K1* to the kernel traits *K2* using *Converter* to do the conversion. Those traits must be of the form *Cartesian*<*FT1*> and *Cartesian*<*FT2*> (or the equivalent with *Simple_cartesian*). It then provides the following operators to convert objects from *K1* to *K2*.

The third template parameter *NTConverter* is a function object that must provide *K2::FT operator()(K1::FT n)* that converts *n* to an *K2::FT* which has the same value.

The default value of this parameter is *CGAL::NT_converter*<*K1::FT*, *K2::FT*>.

```
#include <CGAL/Cartesian_converter.h>
```

Creation

```
Cartesian_converter<K1, K2, NTConverter> conv;
```

Default constructor.

Operations

```
K2::Point_2                      conv.operator()( K1::Point_2 p)
```

returns a *K2::Point_2* which coordinates are those of *p*, converted by *NTConverter*.

Similar operators are defined for the other kernel traits types *Point_3*, *Vector_2*...

See Also

CGAL::Cartesian<*FieldNumberType*> page [41](#)

CGAL::cartesian_to_homogeneous

```
#include <CGAL/cartesian_homogeneous_conversion.h>
```

```
Point_2< Homogeneous<RT> > cartesian_to_homogeneous( Point_2< Cartesian<RT> > cp)
```

converts 2d point *cp* with Cartesian representation into a 2d point with homogeneous representation with the same number type.

```
Point_3< Homogeneous<RT> > cartesian_to_homogeneous( Point_3< Cartesian<RT> > cp)
```

converts 3d point *cp* with Cartesian representation into a 3d point with homogeneous representation with the same number type.

CGAL::Filtered_kernel<CK>

Definition

Filtered_kernel<CK> is a kernel that uses the filtering technique [BBP01] to achieve a kernel with exact and efficient predicates. The geometric constructions are exactly those of the kernel *CK*, which means that they are not necessarily exact.

Is Model for the Concepts

Kernel

```
#include <CGAL/Filtered_kernel.h>
```

Example

The following example shows how to produce a kernel whose geometric objects and constructions are those of *Simple_cartesian<double>* but the predicates are exact.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel<CK> K;
```

Implementation

The implementation uses *CGAL::Filtered_predicate<EP, FP, C2E, C2F>* over each predicate of the kernel traits interface. Additionally, faster static filters are used for a few selected critical predicates. The static filters can be disabled by compiling with *-DCGAL_NO_STATIC_FILTERS*.

CGAL::Filtered_kernel_adaptor<CK>

Definition

Filtered_kernel_adaptor<CK> is a kernel that uses the filtering technique [BBP01] to obtain a kernel with exact and efficient predicate functors. The geometric constructions are exactly those of the kernel CK, which means that they are not necessarily exact.

In contrast to *Filtered_kernel*, the global functions are those of CK.

Is Model for the Concepts

Kernel

```
#include <CGAL/Filtered_kernel.h>
```

Example

The following example shows how to produce a kernel whose geometric objects and constructions are those of *Simple_cartesian*<double>. The predicate functors of the kernel are exact, the global functions are not.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel_adaptor<CK> K;

typedef K::Point_2 p(0,0), q(1,1), r(1,5);

CGAL::orientation(p,q,r);           // not exact

typedef K::Orientation_2 orientation;
orientation(p,q,r);                 // exact
```

CGAL::Filtered_predicate<EP, FP, C2E, C2F>

Definition

Filtered_predicate<EP, FP, C2E, C2F> is an adaptor for predicate function objects that allows one to produce efficient and exact predicates. It is used to build *CGAL::Filtered_kernel*<CK, EK, FK, C2E, C2F> and can be used for other predicates too.

EP is the exact but supposedly slow predicate that is able to evaluate the predicate correctly. It will be called only when the filtering predicate, FP, cannot compute the correct result. This failure of FP must be done by throwing an exception.

To convert the geometric objects that are the arguments of the predicate, we use the function objects C2E and C2F, which must be of the form *Cartesian_converter* or *Homogeneous_converter*.

```
#include <CGAL/Filtered_predicate.h>
```

Types

```
typedef FP::result_type    result_type;
```

The return type of the function operators. It must also be the same type as *EP::result_type*.

Creation

```
Filtered_predicate<EP, FP, C2E, C2F> fo;
```

Default constructor.

Operations

```
template <class A1>
result_type    fo.operator()( A1 a1)
```

The unary function operator for unary predicates.

```
template <class A1, class A2>
result_type    fo.operator()( A1 a1, A2 a2)
```

The binary function operator for binary predicates.

Similar function operators are defined for up to 7 arguments.

Example

The following example defines an efficient and exact version of the orientation predicate over three points using the Cartesian representation with double coordinates and without reference counting (*Simple_cartesian*<*double*>::*Point_2*). Of course, the orientation predicate can already be found in the kernel, but you can follow this example to filter your own predicates. It uses the fast but inexact predicate based on interval arithmetic for filtering and the slow but exact predicate based on multi-precision floats when the filtering predicate fails.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_predicate.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Cartesian_converter.h>

typedef CGAL::Simple_cartesian<double> K;
typedef CGAL::Simple_cartesian<CGAL::Interval_nt_advanced> FK;
typedef CGAL::Simple_cartesian<CGAL::MP_Float> EK;
typedef CGAL::Cartesian_converter<K, EK> C2E;
typedef CGAL::Cartesian_converter<K, FK> C2F;

// Define my predicate, parameterized by a kernel.
template < typename K >
struct My_orientation_2
{
    typedef typename K::RT      RT;
    typedef typename K::Point_2 Point_2;

    CGAL::Orientation
    operator()(const Point_2 &p, const Point_2 &q, const Point_2 &r) const
    {
        RT prx = p.x() - r.x();
        RT pry = p.y() - r.y();
        RT qrx = q.x() - r.x();
        RT qry = q.y() - r.y();
        return static_cast<CGAL::Orientation> ( CGAL::sign( prx*qry - qrx*pry ) );
    }
};

typedef CGAL::Filtered_predicate<My_orientation_2<EK>,
                                My_orientation_2<FK>, C2E, C2F> Orientation_2;

int main()
{
    K::Point_2 p(1,2), q(2,3), r(3,4);
    Orientation_2 orientation;
    orientation(p, q, r);
    return 0;
}

```

CGAL::Homogeneous<RingNumberType>

```
#include <CGAL/Homogeneous.h>
```

Definition

A model for a *Kernel* using homogeneous coordinates to represent the geometric objects. In order for *Homogeneous<RingNumberType>* to model Euclidean geometry in E^2 and/or E^3 , for some mathematical ring E (e.g., the integers \mathbb{Z} or the rationals \mathbb{Q}), the template parameter *RingNumberType* must model the mathematical ring E . That is, the ring operations on this number type must compute the mathematically correct results. If the number type provided as a model for *RingNumberType* is only an approximation of a ring (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

Kernel page [35](#)

Types

```
typedef Quotient<RingNumberType>    FT;
typedef RingNumberType               RT;
```

Implementation

This model of a kernel uses reference counting.

CGAL::Homogeneous_converter<K1, K2, RTConverter, FTConverter>

Definition

Homogeneous_converter<*K1*, *K2*, *RTConverter*, *FTConverter*> converts objects from the kernel traits *K1* to the kernel traits *K2*. Those traits must be of the form *Homogeneous*<*RT1*> and *Homogeneous*<*RT2*> (or the equivalent with *Simple_homogeneous*). It then provides the following operators to convert objects from *K1* to *K2*.

The third template parameter *RT_Converter* is a function object that must provide *K2::RT operator()(const K1::RT &n)*; that converts *n* to an *K2::RT* that has the same value.

The default value of this parameter is *CGAL::NT_converter*<*K1::RT*, *K2::RT*>, which uses the conversion operator from *K1::RT* to *K2::RT*.

Similarly, the fourth template parameter must provide *K2::FT operator()(const K1::FT &n)*; that converts *n* to an *K2::FT* that has the same value. Its default value is *CGAL::NT_converter*<*K1::FT*, *K2::FT*>.

#include <CGAL/Homogeneous_converter.h>

Creation

Homogeneous_converter<*K1*, *K2*, *RTConverter*, *FTConverter*> *conv*;

Default constructor.

Operations

K2::Point_2 *conv.operator()(K1::Point_2 p)*

returns a *K2::Point_2* which coordinates are those of *p*, converted by *RTConverter*.

Similar operators are defined for the other kernel traits geometric types *Point_3*, *Vector_2*...

CGAL::homogeneous_to_cartesian

```
#include <CGAL/cartesian_homogeneous_conversion.h>
```

```
Point_2< Cartesian<FT> >      homogeneous_to_cartesian( Point_2< Homogeneous<FT> > hp)
```

converts 2d point *hp* with homogeneous representation into a 2d point with Cartesian representation with the same number type.

```
Point_3< Cartesian<FT> >      homogeneous_to_cartesian( Point_3< Homogeneous<FT> > hp)
```

converts 3d point *hp* with homogeneous representation into a 3d point with Cartesian representation with the same number type.

CGAL::Kernel_archetype

Definition

CGAL::Kernel_archetype is a concept archetype (minimal model) for the CGAL kernel concept. It provides all functionality required by the CGAL kernel concept, but nothing more. It can be used for testing successful compilation of packages of the basic library with a minimal model. Deprecated kernel functionality is not supported. All geometrical types (like the 2d/3d point or segment types) of *CGAL::Kernel_archetype* have copy constructors, default constructors and an assignment operator, and nothing else. Comparison operators are by default not supported, but can be switched on by defining the macro *CGAL_CONCEPT_ARCHETYPE_ALLOW_COMPARISONS*.

The geometrical types of the concept archetype encapsulate no data members, so runtime checks with the archetype are not very useful (*CGAL::Kernel_archetype* is only meant for compilation checks with a minimal model in the testsuites of CGAL packages).

The package supports the two- and three-dimensional part of the CGAL kernel concept. The d-dimensional part is not supported.

CGAL::Kernel_archetype normally offers the full functionality (all types, functors and constructions of a CGAL kernel model), but it is possible to restrict the interface. This can be useful for testing packages that require only a very small subset of the functionality offered by CGAL kernel models. If you want to do this, you have to define the macro *CGAL_CA_LIMITED_INTERFACE* (before the inclusion of *CGAL/Kernel_archetype.h*) to switch on the interface limitation. Now you have to tell the kernel archetype the types it has to provide for the specific package.

For every type you have to define a macro. The name of the macro is `CGAL_CA_NAME_OF_KERNEL_TYPE`, where `NAME_OF_KERNEL_TYPE` is the name of the kernel type (written in capitals) that has to be provided by the kernel archetype for a specific package. If, for example, a package only needs type definitions for `Point_2` and `Orientation_2`, you would define `CGAL_CA_LIMITED_INTERFACE`, `CGAL_CA_POINT_2` and `CGAL_CA_ORIENTATION_2`.

Is Model for the Concepts

Kernel page 35

```
#include <CGAL/Kernel_archetype.h>
```

Creation

<i>Kernel_archetype</i> <i>ka</i> ;	Default constructor.
-------------------------------------	----------------------

Types

We provide all type definitions that must be provided by a CGAL kernel model. See the CGAL kernel concept manual pages for details. Deprecated functionality is not supported. You can restrict the interface by defining macros (see the definition for details).

Operations

For each of the function objects of the kernel archetype, there is a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended.

CGAL::Kernel_traits<T>

Definition

The class *Kernel_traits*<*T*> provides access to the kernel model to which the argument type *T* belongs. (Provided *T* belongs to some kernel model.) The default implementation assumes there is a local type *T::Kernel* referring to the kernel model of *T*. If this type does not exist, a specialization of *Kernel_traits*<*T*> can be used to provide the desired information.

This class is, for example, useful in the following context. Assume you want to write a generic function that accepts two points *p* and *q* as argument and constructs the line segment between *p* and *q*. In order to specify the return type of this function, you need to know what is the segment type corresponding to the Point type representing *p* and *q*. Using *Kernel_traits*<*T*>, this can be done as follows.

```
template < class Point >
typename Kernel_traits<Point>::Kernel::Segment
construct_segment(Point p, Point q)
{ ... }
```

Types

<i>typedef T::R</i>	<i>Kernel</i> ;	If <i>T</i> is a type <i>K::Point_2</i> of some kernel model <i>K</i> , then <i>Kernel</i> is equal to <i>K</i> .
---------------------	-----------------	-------------------------------------------------------------------------------------------------------------------

CGAL::Simple_cartesian<FieldNumberType>

```
#include <CGAL/Simple_cartesian.h>
```

Definition

A model for a *Kernel* using Cartesian coordinates to represent the geometric objects. In order for *Simple_cartesian*<FieldNumberType> to model Euclidean geometry in E^2 and/or E^3 , for some mathematical field E (e.g., the rationals \mathbb{Q} or the reals \mathbb{R}), the template parameter FieldNumberType must model the mathematical field E . That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for FieldNumberType is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

Kernel page [35](#)

Types

```
typedef FieldNumberType
```

```
FT;
```

```
typedef FieldNumberType
```

```
RT;
```

Implementation

In contrast to *Cartesian*, no reference counting is used internally. This eases debugging, but may slow down algorithms that copy objects intensively.

2.10 Kernel Objects

2.10.1 Two-dimensional Objects

CGAL::Aff_transformation_2<Kernel>

Definition

The class *Aff_transformation_2<Kernel>* represents two-dimensional affine transformations. The general form of an affine transformation is based on a homogeneous representation of points. Thereby all transformations can be realized by matrix multiplications.

Multiplying the transformation matrix by a scalar does not change the represented transformation. Therefore, any transformation represented by a matrix with rational entries can be represented by a transformation matrix with integer entries as well. (Multiply the matrix with the common denominator of the rational entries.) Hence, it is sufficient to use the number type *Kernel::RT* to represent the entries of the transformation matrix.

CGAL offers several specialized affine transformations. Different constructors are provided to create them. They are parameterized with a symbolic name to denote the transformation type, followed by additional parameters. The symbolic name tags solve ambiguities in the function overloading and they make the code more readable, i.e., what type of transformation is created.

Since two-dimensional points have three homogeneous coordinates, we have a 3×3 matrix $(m_{ij})_{i,j=0\dots 2}$.

If the homogeneous representations are normalized (the homogenizing coordinate is 1), then the upper left 2×2 matrix realizes linear transformations. In the matrix form of a translation, the translation vector $(v_0, v_1, 1)$ appears in the last column of the matrix. The entries m_{20} and m_{21} are always zero and therefore do not appear in the constructors.

Creation

```
Aff_transformation_2<Kernel> t( Identity_transformation);
```

introduces an identity transformation.

```
Aff_transformation_2<Kernel> t( const Translation, Vector_2<Kernel> v);
```

introduces a translation by a vector v .

```
Aff_transformation_2<Kernel> t( const Rotation,  
                                Direction_2<Kernel> d,  
                                Kernel::RT num,
```

Kernel::RT den = RT(1)

approximates the rotation over the angle indicated by direction d , such that the differences between the sines and cosines of the rotation given by d and the approximating rotation are at most num/den each.

Precondition: $num/den > 0$.

Aff_transformation_2<Kernel> t(const Rotation,
Kernel::RT sine_rho,
Kernel::RT cosine_rho,
Kernel::RT hw = RT(1))

introduces a rotation by the angle ρ .

Precondition: $sine_rho^2 + cosine_rho^2 == hw^2$.

Aff_transformation_2<Kernel> t(const Scaling, Kernel::RT s, Kernel::RT hw = RT(1));

introduces a scaling by a scale factor s/hw .

Aff_transformation_2<Kernel> t(Kernel::RT m00,
Kernel::RT m01,
Kernel::RT m02,
Kernel::RT m10,
Kernel::RT m11,
Kernel::RT m12,
Kernel::RT hw = RT(1))

introduces a general affine transformation in the $3 \times$

3 matrix form $\begin{pmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ 0 & 0 & hw \end{pmatrix}$. The sub-matrix

$\frac{1}{hw} \begin{pmatrix} m_{00} & m_{01} \\ m_{10} & m_{11} \end{pmatrix}$ contains the scaling and rotation information,

the vector $\frac{1}{hw} \begin{pmatrix} m_{02} \\ m_{12} \end{pmatrix}$ contains the translational part of the transformation.

Aff_transformation_2<Kernel> t(Kernel::RT m00,
Kernel::RT m01,
Kernel::RT m10,
Kernel::RT m11,
Kernel::RT hw = RT(1))

introduces a general linear transformation

$\begin{pmatrix} m_{00} & m_{01} & 0 \\ m_{10} & m_{11} & 0 \\ 0 & 0 & hw \end{pmatrix}$, i.e. there is no translational

part.

Operations

The main thing to do with transformations is to apply them on geometric objects. Each class *Class_2<Kernel>* representing a geometric object has a member function:

Class_2<Kernel> *transform*(*Aff_transformation_2<Kernel>* *t*).

The transformation classes provide a member function *transform()* for points, vectors, directions, and lines:

<i>Point_2<Kernel></i>	<i>t.transform(Point_2<Kernel> p)</i>
<i>Vector_2<Kernel></i>	<i>t.transform(Vector_2<Kernel> p)</i>
<i>Direction_2<Kernel></i>	<i>t.transform(Direction_2<Kernel> p)</i>
<i>Line_2<Kernel></i>	<i>t.transform(Line_2<Kernel> p)</i>

CGAL provides function operators for these member functions:

<i>Point_2<Kernel></i>	<i>t.operator()(Point_2<Kernel> p)</i>
<i>Vector_2<Kernel></i>	<i>t.operator()(Vector_2<Kernel> p)</i>
<i>Direction_2<Kernel></i>	<i>t.operator()(Direction_2<Kernel> p)</i>
<i>Line_2<Kernel></i>	<i>t.operator()(Line_2<Kernel> p)</i>

Miscellaneous

Aff_transformation_2<Kernel>

<i>t.operator*(s)</i>	composes two affine transformations.
------------------------	--------------------------------------

Aff_transformation_2<Kernel>

<i>t.inverse()</i>	gives the inverse transformation.
--------------------	-----------------------------------

<i>bool</i>	<i>t.is_even()</i>	returns <i>true</i> , if the transformation is not reflecting, i.e. the determinant of the involved linear transformation is non-negative.
-------------	--------------------	--------------------------------------------------------------------------------------------------------------------------------------------

<i>bool</i>	<i>t.is_odd()</i>	returns <i>true</i> , if the transformation is reflecting.
-------------	-------------------	------------------------------------------------------------

The matrix entries of a matrix representation of a *Aff_transformation_2<Kernel>* can be accessed through the following member functions:

<i>Kernel::FT</i>	<i>t.cartesian(int i, int j)</i>	returns entry m_{ij} in a matrix representation in which m_{22} is 1.
<i>Kernel::FT</i>	<i>t.m(int i, int j)</i>	

<i>Kernel::RT</i>	<i>t.homogeneous(int i, int j)</i>	returns entry m_{ij} in some fixed matrix representation.
<i>Kernel::RT</i>	<i>t.hm(int i, int j)</i>	

For affine transformations no I/O operators are defined.

See Also

Identity_transformation, Rotation, Scaling, Translation
rational_rotation_approximation

Example

```
typedef Cartesian<double>      K;
typedef Aff_transformation_2<K> Transformation;
typedef Point_2<K>            Point;
typedef Vector_2<K>           Vector;
typedef Direction_2<K>        Direction;

Transformation rotate(ROTATION, sin(pi), cos(pi));
Transformation rational_rotate(ROTATION, Direction(1,1), 1, 100);
Transformation translate(TRANSLATION, Vector(-2, 0));
Transformation scale(SCALING, 3);

Point q(0, 1);
q = rational_rotate(q);

Point p(1, 1);

p = rotate(p);

p = translate(p);

p = scale(p);
```

The same would have been achieved with

```
Transformation transform = scale * (translate * rotate);
p = transform(Point(1.0, 1.0));
```

CGAL::Bbox_2

#include <CGAL/Bbox_2.h>

Definition

An object b of the class *Bbox_2* is a bounding box in the two-dimensional Euclidean plane \mathbb{E}^2 . This class is not templated.

Creation

Bbox_2 b (*double* x_min , *double* y_min , *double* x_max , *double* y_max);

introduces a bounding box b with lower left corner at $(xmin, ymin)$ and with upper right corner at $(xmax, ymax)$.

Operations

double $b.xmin()$

double $b.ymin()$

double $b.xmax()$

double $b.ymax()$

Bbox_2 $b.operator+(c)$ returns a bounding box of b and c .

CGAL::Circle_2<Kernel>

Definition

An object of type *Circle_2<Kernel>* is a circle in the two-dimensional Euclidean plane \mathbb{E}^2 . The circle is oriented, i.e. its boundary has clockwise or counterclockwise orientation. The boundary splits \mathbb{E}^2 into a positive and a negative side, where the positive side is to the left of the boundary. The boundary also splits \mathbb{E}^2 into a bounded and an unbounded side. Note that the circle can be degenerated, i.e. the squared radius may be zero.

Creation

Circle_2<Kernel> *c*(*Point_2<Kernel>* *center*,
Kernel::FT *squared_radius*,
Orientation *ori* = *COUNTERCLOCKWISE*)

introduces a variable *c* of type *Circle_2<Kernel>*. It is initialized to the circle with center *center*, squared radius *squared_radius* and orientation *ori*.
Precondition: *ori* \neq *COLLINEAR*, and further, *squared_radius* \geq 0.

Circle_2<Kernel> *c*(*Point_2<Kernel>* *p*, *Point_2<Kernel>* *q*, *Point_2<Kernel>* *r*);

introduces a variable *c* of type *Circle_2<Kernel>*. It is initialized to the unique circle which passes through the points *p*, *q* and *r*. The orientation of the circle is the orientation of the point triple *p*, *q*, *r*.
Precondition: *p*, *q*, and *r* are not collinear.

Circle_2<Kernel> *c*(*Point_2<Kernel>* *p*, *Point_2<Kernel>* *q*, *Orientation* *ori* = *COUNTERCLOCKWISE*);

introduces a variable *c* of type *Circle_2<Kernel>*. It is initialized to the circle with diameter \overline{pq} and orientation *ori*.
Precondition: *ori* \neq *COLLINEAR*.

Circle_2<Kernel> *c*(*Point_2<Kernel>* *center*, *Orientation* *ori* = *COUNTERCLOCKWISE*);

introduces a variable *c* of type *Circle_2<Kernel>*. It is initialized to the circle with center *center*, squared radius zero and orientation *ori*.
Precondition: *ori* \neq *COLLINEAR*.
Postcondition: *c.is_degenerate()* = *true*.

Access Functions

Point_2<Kernel> *c.center()* returns the center of *c*.

<i>Kernel::FT</i>	<i>c.squared_radius()</i>	returns the squared radius of <i>c</i> .
<i>Orientation</i>	<i>c.orientation()</i>	returns the orientation of <i>c</i> .
<i>bool operator</i>	<i>c.==(circle2)</i>	returns <i>true</i> , iff <i>c</i> and <i>circle2</i> are equal, i.e. if they have the same center, same squared radius and same orientation.
<i>bool operator</i>	<i>c.!=(circle2)</i>	returns <i>true</i> , iff <i>c</i> and <i>circle2</i> are not equal.

Predicates

<i>bool</i>	<i>c.is_degenerate()</i>	returns <i>true</i> , iff <i>c</i> is degenerate, i.e. if <i>c</i> has squared radius zero.
<i>Oriented_side</i>	<i>c.oriented_side(Point_2<Kernel> p)</i>	returns either the constant <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_POSITIVE_SIDE</i> , or <i>ON_NEGATIVE_SIDE</i> , iff <i>p</i> lies on the boundary, properly on the positive side, or properly on the negative side of <i>c</i> , resp.
<i>Bounded_side</i>	<i>c.bounded_side(Point_2<Kernel> p)</i>	returns <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> , or <i>ON_UNBOUNDED_SIDE</i> iff <i>p</i> lies properly inside, on the boundary, or properly outside of <i>c</i> , resp.
<i>bool</i>	<i>c.has_on_positive_side(Point_2<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_negative_side(Point_2<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_boundary(Point_2<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_bounded_side(Point_2<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_unbounded_side(Point_2<Kernel> p)</i>	

Miscellaneous

<i>Circle_2<Kernel></i>	<i>c.opposite()</i>	returns the circle with the same center and squared radius as <i>c</i> but with opposite orientation.
<i>Circle_2<Kernel></i>	<i>c.orthogonal_transform(Aff_transformation_2<Kernel> at)</i>	returns the circle obtained by applying <i>at</i> on <i>c</i> . <i>Precondition:</i> <i>at</i> is an orthogonal transformation.
<i>Bbox_2</i>	<i>c.bbox()</i>	returns a bounding box containing <i>c</i> .

CGAL::Direction_2<Kernel>

Definition

An object of the class *Direction_2<Kernel>* is a vector in the two-dimensional vector space \mathbb{R}^2 where we forget about its length. They can be viewed as unit vectors, although there is no normalization internally, since this is error prone. Directions are used whenever the length of a vector does not matter. They also characterize a set of parallel oriented lines that have the same orientations. For example, you can ask for the direction orthogonal to an oriented plane, or the direction of an oriented line. Further, they can be used to indicate angles. The slope of a direction is $dy()/dx()$.

Creation

Direction_2<Kernel> *d*(*Vector_2<Kernel>* *v*); introduces the direction *d* of vector *v*.

Direction_2<Kernel> *d*(*Line_2<Kernel>* *l*); introduces the direction *d* of line *l*.

Direction_2<Kernel> *d*(*Ray_2<Kernel>* *r*); introduces the direction *d* of ray *r*.

Direction_2<Kernel> *d*(*Segment_2<Kernel>* *s*); introduces the direction *d* of segment *s*.

Direction_2<Kernel> *d*(*Kernel::RT* *x*, *Kernel::RT* *y*);
introduces a direction *d* passing through the origin and the point with Cartesian coordinates (*x*,*y*).

Operations

Kernel::RT *d*.delta(*int* *i*) returns values, such that *d*== *Direction_2<Kernel>*(delta(0),delta(1)).
Precondition: : $0 \leq i \leq 1$.

Kernel::RT *d*.dx() returns delta(0).

Kernel::RT *d*.dy() returns delta(1).

There is a total order on directions. We compare the angles between the positive *x*-axis and the directions in counterclockwise order.

bool *d*.operator==(*e*)
bool *d*.operator!=(*e*)
bool *d*.operator<(*e*)
bool *d*.operator>(*e*)
bool *d*.operator<=(*e*)
bool *d*.operator>=(*e*)

Furthermore, we have

<i>bool</i>	<i>d.counterclockwise_in_between(d1, d2)</i>	returns true, iff <i>d</i> is not equal to <i>d1</i> , and while rotating counterclockwise starting at <i>d1</i> , <i>d</i> is reached strictly before <i>d2</i> is reached. Note that true is returned if <i>d1</i> == <i>d2</i> , unless also <i>d</i> == <i>d1</i> .
-------------	-----------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>Direction_2<Kernel></i>	<i>d.operator-()</i>	The direction opposite to <i>d</i> .
----------------------------------	----------------------	--------------------------------------

Miscellaneous

<i>Vector_2<Kernel></i>	<i>d.vector()</i>	returns a vector that has the same direction as <i>d</i> .
-------------------------------	-------------------	------------------------------------------------------------

<i>Direction_2<Kernel></i>	<i>d.transform(Aff_transformation_2<Kernel> t)</i>	returns the direction obtained by applying <i>t</i> on <i>d</i> .
----------------------------------	-----------------------------------------------------------	-------------------------------------------------------------------

Kernel::Direction_2 page [351](#)

CGAL::Iso_rectangle_2<Kernel>

Definition

An object s of the data type *Iso_rectangle_2<Kernel>* is a rectangle in the Euclidean plane \mathbb{E}^2 with sides parallel to the x and y axis of the coordinate system.

Although they are represented in a canonical form by only two vertices, namely the lower left and the upper right vertex, we provide functions for “accessing” the other vertices as well. The vertices are returned in counterclockwise order.

Iso-oriented rectangles and bounding boxes are quite similar. The difference however is that bounding boxes have always double coordinates, whereas the coordinate type of an iso-oriented rectangle is chosen by the user.

Creation

Iso_rectangle_2<Kernel> r (*Point_2<Kernel>* p , *Point_2<Kernel>* q);

introduces an iso-oriented rectangle r with diagonal opposite vertices p and q . Note that the object is brought in the canonical form.

Iso_rectangle_2<Kernel> r (*Point_2<Kernel>* $left$,
Point_2<Kernel> $right$,
Point_2<Kernel> $bottom$,
Point_2<Kernel> top)

introduces an iso-oriented rectangle r whose minimal x coordinate is the one of $left$, the maximal x coordinate is the one of $right$, the minimal y coordinate is the one of $bottom$, the maximal y coordinate is the one of top .

Iso_rectangle_2<Kernel> r (*Kernel::RT* min_hx ,
Kernel::RT min_hy ,
Kernel::RT max_hx ,
Kernel::RT max_hy ,
Kernel::RT $hw = RT(1)$)

introduces an iso-oriented rectangle r with diagonal opposite vertices $(min_hx/hw, min_hy/hw)$ and $(max_hx/hw, max_hy/hw)$.
Precondition: $hw \neq 0$.

Operations

bool $r.operator==(r2)$ Test for equality: two iso-oriented rectangles are equal, iff their lower left and their upper right vertices are equal.

<i>bool</i>	<i>r.operator!=(r2)</i>	Test for inequality.
<i>Point_2<Kernel></i>	<i>r.vertex(int i)</i>	returns the <i>i</i> 'th vertex modulo 4 of <i>r</i> in counterclockwise order, starting with the lower left vertex.
<i>Point_2<Kernel></i>	<i>r.operator[](int i)</i>	returns <i>vertex(i)</i> .
<i>Point_2<Kernel></i>	<i>r.min()</i>	returns the lower left vertex of <i>r</i> ($= vertex(0)$).
<i>Point_2<Kernel></i>	<i>r.max()</i>	returns the upper right vertex of <i>r</i> ($= vertex(2)$).
<i>Kernel::FT</i>	<i>r.xmin()</i>	returns the <i>x</i> coordinate of lower left vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.ymin()</i>	returns the <i>y</i> coordinate of lower left vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.xmax()</i>	returns the <i>x</i> coordinate of upper right vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.ymax()</i>	returns the <i>y</i> coordinate of upper right vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.min_coord(int i)</i>	returns the <i>i</i> 'th Cartesian coordinate of the lower left vertex of <i>r</i> . <i>Precondition:</i> $0 \leq i \leq 1$.
<i>Kernel::FT</i>	<i>r.max_coord(int i)</i>	returns the <i>i</i> 'th Cartesian coordinate of the upper right vertex of <i>r</i> . <i>Precondition:</i> $0 \leq i \leq 1$.

Predicates

<i>bool</i>	<i>r.is_degenerate()</i>	<i>r</i> is degenerate, if all vertices are collinear.
<i>Bounded_side</i>	<i>r.bounded_side(Point_2<Kernel> p)</i>	returns either <i>ON_UNBOUNDED_SIDE</i> , <i>ON_BOUNDED_SIDE</i> , or the constant <i>ON_BOUNDARY</i> , depending on where point <i>p</i> is.
<i>bool</i>	<i>r.has_on_boundary(Point_2<Kernel> p)</i>	
<i>bool</i>	<i>r.has_on_bounded_side(Point_2<Kernel> p)</i>	
<i>bool</i>	<i>r.has_on_unbounded_side(Point_2<Kernel> p)</i>	

Miscellaneous

<i>Kernel::FT</i>	<i>r.area()</i>	returns the area of <i>r</i> .
<i>Bbox</i>	<i>r.bbox()</i>	returns a bounding box containing <i>r</i> .

Iso_rectangle_2<Kernel>

r.transform(Aff_transformation_2<Kernel> *t*)

returns the iso-oriented rectangle obtained by applying *t* on the lower left and the upper right corner of *r*.

Precondition: The angle at a rotation must be a multiple of $\pi/2$, otherwise the resulting rectangle does not have the same side length. Note that rotating about an arbitrary angle can even result in a degenerate iso-oriented rectangle.

Kernel::IsoRectangle_2.....page [382](#)

CGAL::Line_2<Kernel>

Definition

An object l of the data type $Line_2<Kernel>$ is a directed straight line in the two-dimensional Euclidean plane \mathbb{E}^2 . It is defined by the set of points with Cartesian coordinates (x, y) that satisfy the equation

$$l : ax + by + c = 0.$$

The line splits \mathbb{E}^2 in a *positive* and a *negative* side. A point p with Cartesian coordinates (px, py) is on the positive side of l , iff $apx + bpy + c > 0$, it is on the negative side of l , iff $apx + bpy + c < 0$. The positive side is to the left of l .

Creation

$Line_2<Kernel> \ l(Kernel::RT \ a, Kernel::RT \ b, Kernel::RT \ c);$

introduces a line l with the line equation in Cartesian coordinates $ax + by + c = 0$.

$Line_2<Kernel> \ l(Point_2<Kernel> \ p, Point_2<Kernel> \ q);$

introduces a line l passing through the points p and q . Line l is directed from p to q .

$Line_2<Kernel> \ l(Point_2<Kernel> \ p, Direction_2<Kernel> \ d);$

introduces a line l passing through point p with direction d .

$Line_2<Kernel> \ l(Point_2<Kernel> \ p, Vector_2<Kernel> \ v);$

introduces a line l passing through point p and oriented by v .

$Line_2<Kernel> \ l(Segment_2<Kernel> \ s);$

introduces a line l supporting the segment s , oriented from source to target.

$Line_2<Kernel> \ l(Ray_2<Kernel> \ r);$

introduces a line l supporting the ray r , with same orientation.

Operations

$bool \quad \quad \quad l.operator==(h)$

Test for equality: two lines are equal, iff they have a non empty intersection and the same direction.

<i>bool</i>	<i>l.operator!=(h)</i>	Test for inequality.
<i>Kernel::RT</i>	<i>l.a()</i>	returns the first coefficient of <i>l</i> .
<i>Kernel::RT</i>	<i>l.b()</i>	returns the second coefficient of <i>l</i> .
<i>Kernel::RT</i>	<i>l.c()</i>	returns the third coefficient of <i>l</i> .
<i>Point_2<Kernel></i>	<i>l.point(int i)</i>	returns an arbitrary point on <i>l</i> . It holds <i>point(i) == point(j)</i> , iff <i>i==j</i> . Furthermore, <i>l</i> is directed from <i>point(i)</i> to <i>point(j)</i> , for all <i>i < j</i> .
<i>Point_2<Kernel></i>	<i>l.projection(Point_2<Kernel> p)</i>	returns the orthogonal projection of <i>p</i> onto <i>l</i> .
<i>Kernel::FT</i>	<i>l.x_at_y(Kernel::FT y)</i>	returns the <i>x</i> -coordinate of the point at <i>l</i> with given <i>y</i> -coordinate. <i>Precondition: l</i> is not horizontal.
<i>Kernel::FT</i>	<i>l.y_at_x(Kernel::FT x)</i>	returns the <i>y</i> -coordinate of the point at <i>l</i> with given <i>x</i> -coordinate. <i>Precondition: l</i> is not vertical.

Predicates

<i>bool</i>	<i>l.is_degenerate()</i>	line <i>l</i> is degenerate, if the coefficients <i>a</i> and <i>b</i> of the line equation are zero.
<i>bool</i>	<i>l.is_horizontal()</i>	
<i>bool</i>	<i>l.is_vertical()</i>	
<i>Oriented_side</i>	<i>l.oriented_side(Point_2<Kernel> p)</i>	returns <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_NEGATIVE_SIDE</i> , or the constant <i>ON_POSITIVE_SIDE</i> , depending on the position of <i>p</i> relative to the oriented line <i>l</i> .

For convenience we provide the following boolean functions:

<i>bool</i>	<i>l.has_on(Point_2<Kernel> p)</i>
<i>bool</i>	<i>l.has_on_positive_side(Point_2<Kernel> p)</i>
<i>bool</i>	<i>l.has_on_negative_side(Point_2<Kernel> p)</i>

Miscellaneous

<i>Vector_2<Kernel></i>	<i>l.to_vector()</i>	returns a vector having the direction of <i>l</i> .
<i>Direction_2<Kernel></i>	<i>l.direction()</i>	returns the direction of <i>l</i> .

<i>Line_2</i> < <i>Kernel</i> >	<i>l.opposite()</i>	returns the line with opposite direction.
<i>Line_2</i> < <i>Kernel</i> >	<i>l.perpendicular(Point_2</i> < <i>Kernel</i> > <i>p</i>)	returns the line perpendicular to <i>l</i> and passing through <i>p</i> , where the direction is the direction of <i>l</i> rotated counterclockwise by 90 degrees.
<i>Line_2</i> < <i>Kernel</i> >	<i>l.transform(Aff_transformation_2</i> < <i>Kernel</i> > <i>t</i>)	returns the line obtained by applying <i>t</i> on a point on <i>l</i> and the direction of <i>l</i> .

Example

Let us first define two Cartesian two-dimensional points in the Euclidean plane \mathbb{E}^2 . Their dimension and the fact that they are Cartesian is expressed by the suffix *_2* and the representation type *Cartesian*.

```
Point_2< Cartesian<double> >  p(1.0,1.0), q(4.0,7.0);
```

To define a line *l* we write:

```
Line_2< Cartesian<double> >  l(p,q);
```

Kernel::Line_2 page [399](#)

CGAL::Point_2<Kernel>

Definition

An object of the class *Point_2<Kernel>* is a point in the two-dimensional Euclidean plane \mathbb{E}^2 .

Remember that *Kernel::RT* and *Kernel::FT* denote a *RingNumberType* and a *FieldNumberType*, respectively. For the kernel model *Cartesian<T>*, the two types are the same. For the kernel model *Homogeneous<T>*, *Kernel::RT* is equal to *T*, and *Kernel::FT* is equal to *Quotient<T>*.

Types

Point_2<Kernel>::Cartesian_const_iterator

An iterator for enumerating the Cartesian coordinates of a point.

Creation

Point_2<Kernel> p(Origin ORIGIN);

introduces a variable *p* with Cartesian coordinates (0,0).

Point_2<Kernel> p(Kernel::RT hx, Kernel::RT hy, Kernel::RT hw = RT(1));

introduces a point *p* initialized to (*hx/hw*, *hy/hw*).
Precondition: *hw* \neq *Kernel::RT*(0)

Operations

bool p.operator==(q)

Test for equality. Two points are equal, iff their *x* and *y* coordinates are equal. The point can be compared with *ORIGIN*.

bool p.operator!=(q)

Test for inequality. The point can be compared with *ORIGIN*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT p.hx()

returns the homogeneous *x* coordinate.

<i>Kernel::RT</i>	<i>p.hy()</i>	
		returns the homogeneous y coordinate.
<i>Kernel::RT</i>	<i>p.hw()</i>	

returns the homogenizing coordinate.

Note that you do not lose information with the homogeneous representation, because the `FieldNumberType` is a quotient.

<i>Kernel::FT</i>	<i>p.x()</i>	returns the Cartesian x coordinate, that is hx/hw .
<i>Kernel::FT</i>	<i>p.y()</i>	returns the Cartesian y coordinate, that is hy/hw .

The following operations are for convenience and for compatibility with higher dimensional points. Again they come in a Cartesian and in a homogeneous flavor.

<i>Kernel::RT</i>	<i>p.homogeneous(int i)</i>	
		returns the i 'th homogeneous coordinate of p , starting with 0. <i>Precondition:</i> $0 \leq i \leq 2$.

<i>Kernel::FT</i>	<i>p.cartesian(int i)</i>	
		returns the i 'th Cartesian coordinate of p , starting with 0. <i>Precondition:</i> $0 \leq i \leq 1$.

<i>Kernel::FT</i>	<i>p.operator[](int i)</i>	
		returns <i>cartesian</i> (i). <i>Precondition:</i> $0 \leq i \leq 1$.

<i>Cartesian_const_iterator</i>	<i>p.cartesian_begin()</i>	
		returns an iterator to the Cartesian coordinates of p , starting with the 0th coordinate.

<i>Cartesian_const_iterator</i>	<i>p.cartesian_end()</i>	
		returns an off the end iterator to the Cartesian coordinates of p .

<i>int</i>	<i>p.dimension()</i>	
		returns the dimension (the constant 2).

<i>Bbox_2</i>	<i>p.bbox()</i>	
		returns a bounding box containing p . Note that bounding boxes are not parameterized with whatsoever.

Point_2<Kernel> *p.transform(Aff_transformation_2<Kernel> t)*
 returns the point obtained by applying *t* on *p*.

Operators

The following operations can be applied on points:

bool *operator<(p, q)*
 returns true iff *p* is lexicographically smaller than *q*, i.e. either if *p.x()* < *q.x()* or if *p.x()* == *q.x()* and *p.y()* < *q.y()*.

bool *operator>(p, q)*
 returns true iff *p* is lexicographically greater than *q*.

bool *operator<=(p, q)*
 returns true iff *p* is lexicographically smaller or equal to *q*.

bool *operator>=(p, q)*
 returns true iff *p* is lexicographically greater or equal to *q*.

Vector_2<Kernel> *operator-(p, q)*
 returns the difference vector between *q* and *p*. You can substitute *ORIGIN* for either *p* or *q*, but not for both.

Point_2<Kernel> *operator+(p, Vector_2<Kernel> v)*
 returns the point obtained by translating *p* by the vector *v*.

Point_2<Kernel> *operator-(p, Vector_2<Kernel> v)*
 returns the point obtained by translating *p* by the vector -*v*.

Example

The following declaration creates two points with Cartesian double coordinates.

```
Point_2< Cartesian<double> > p, q(1.0, 2.0);
```

The variable `p` is uninitialized and should first be used on the left hand side of an assignment.

```
p = q;  
  
std::cout << p.x() << " " << p.y() << std::endl;
```

CGAL::Ray_2<Kernel>

Definition

An object r of the data type $\text{Ray}_2<\text{Kernel}>$ is a directed straight ray in the two-dimensional Euclidean plane \mathbb{E}^2 . It starts in a point called the *source* of r and goes to infinity.

Creation

$\text{Ray}_2<\text{Kernel}> \ r(\text{Point}_2<\text{Kernel}> \ p, \text{Point}_2<\text{Kernel}> \ q);$

introduces a ray r with source p and passing through point q .

$\text{Ray}_2<\text{Kernel}> \ r(\text{Point}_2<\text{Kernel}> \ p, \text{Direction}_2<\text{Kernel}> \ d);$

introduces a ray r starting at source p with direction d .

$\text{Ray}_2<\text{Kernel}> \ r(\text{Point}_2<\text{Kernel}> \ p, \text{Vector}_2<\text{Kernel}> \ v);$

introduces a ray r starting at source p with the direction of v .

$\text{Ray}_2<\text{Kernel}> \ r(\text{Point}_2<\text{Kernel}> \ p, \text{Line}_2<\text{Kernel}> \ l);$

introduces a ray r starting at source p with the same direction as l .

Operations

<i>bool</i>	$r.operator==(h)$	Test for equality: two rays are equal, iff they have the same source and the same direction.
<i>bool</i>	$r.operator!=(h)$	Test for inequality.
$\text{Point}_2<\text{Kernel}>$	$r.source()$	returns the source of r .
$\text{Point}_2<\text{Kernel}>$	$r.point(\text{int } i)$	returns a point on r . $point(0)$ is the source, $point(i)$, with $i > 0$, is different from the source. <i>Precondition:</i> $i \geq 0$.
$\text{Direction}_2<\text{Kernel}>$	$r.direction()$	returns the direction of r .
$\text{Vector}_2<\text{Kernel}>$	$r.to_vector()$	returns a vector giving the direction of r .

<i>Line_2<Kernel></i>	<i>r.supporting_line()</i>	returns the line supporting <i>r</i> which has the same direction.
<i>Ray_2<Kernel></i>	<i>r.opposite()</i>	returns the ray with the same source and the opposite direction.

Predicates

<i>bool</i>	<i>r.is_degenerate()</i>	ray <i>r</i> is degenerate, if the source and the second defining point fall together (that is if the direction is degenerate).
<i>bool</i> <i>bool</i>	<i>r.is_horizontal()</i> <i>r.is_vertical()</i>	
<i>bool</i>	<i>r.has_on(Point_2<Kernel> p)</i>	A point is on <i>r</i> , iff it is equal to the source of <i>r</i> , or if it is in the interior of <i>r</i> .
<i>bool</i>	<i>r.collinear_has_on(Point_2<Kernel> p)</i>	checks if point <i>p</i> is on <i>r</i> . This function is faster than function <i>has_on()</i> if the precondition checking is disabled. <i>Precondition:</i> <i>p</i> is on the supporting line of <i>r</i> .

Miscellaneous

<i>Ray_2<Kernel></i>	<i>r.transform(Aff_transformation_2<Kernel> t)</i>	returns the ray obtained by applying <i>t</i> on the source and on the direction of <i>r</i> .
----------------------------	-----------------------------------------------------------	------------------------------------------------------------------------------------------------

Kernel::Ray_2 page [412](#)

CGAL::Segment_2<Kernel>

Definition

An object s of the data type $\text{Segment}_2<\text{Kernel}>$ is a directed straight line segment in the two-dimensional Euclidean plane \mathbb{E}^2 , i.e. a straight line segment $[p, q]$ connecting two points $p, q \in \mathbb{R}^2$. The segment is topologically closed, i.e. the end points belong to it. Point p is called the *source* and q is called the *target* of s . The length of s is the Euclidean distance between p and q . Note that there is only a function to compute the square of the length, because otherwise we had to perform a square root operation which is not defined for all number types, which is expensive, and may not be exact.

Creation

$\text{Segment}_2<\text{Kernel}> \ s(\text{Point}_2<\text{Kernel}> \ p, \text{Point}_2<\text{Kernel}> \ q);$

introduces a segment s with source p and target q . The segment is directed from the source towards the target.

Operations

$bool$	$s.operator==(q)$	Test for equality: Two segments are equal, iff their sources and targets are equal.
$bool$	$s.operator!=(q)$	Test for inequality.
$\text{Point}_2<\text{Kernel}>$	$s.source()$	returns the source of s .
$\text{Point}_2<\text{Kernel}>$	$s.target()$	returns the target of s .
$\text{Point}_2<\text{Kernel}>$	$s.min()$	returns the point of s with lexicographically smallest coordinate.
$\text{Point}_2<\text{Kernel}>$	$s.max()$	returns the point of s with lexicographically largest coordinate.
$\text{Point}_2<\text{Kernel}>$	$s.vertex(\text{int } i)$	returns source or target of s : $vertex(0)$ returns the source of s , $vertex(1)$ returns the target of s . The parameter i is taken modulo 2, which gives easy access to the other vertex.
$\text{Point}_2<\text{Kernel}>$	$s.point(\text{int } i)$	returns $vertex(i)$.
$\text{Point}_2<\text{Kernel}>$	$s.operator[] (\text{int } i)$	returns $vertex(i)$.
$\text{Kernel}::FT$	$s.squared_length()$	returns the squared length of s .
$\text{Direction}_2<\text{Kernel}>$	$s.direction()$	returns the direction from source to target of s .

<i>Vector_2<Kernel></i>	<i>s.to_vector()</i>	returns the vector <i>s.target()</i> - <i>s.source()</i> .
<i>Segment_2<Kernel></i>	<i>s.opposite()</i>	returns a segment with source and target point interchanged.
<i>Line_2<Kernel></i>	<i>s.supporting_line()</i>	returns the line <i>l</i> passing through <i>s</i> . Line <i>l</i> has the same orientation as segment <i>s</i> .

Predicates

<i>bool</i>	<i>s.is_degenerate()</i>	segment <i>s</i> is degenerate, if source and target are equal.
<i>bool</i>	<i>s.is_horizontal()</i>	
<i>bool</i>	<i>s.is_vertical()</i>	
<i>bool</i>	<i>s.has_on(Point_2<Kernel> p)</i>	A point is on <i>s</i> , iff it is equal to the source or target of <i>s</i> , or if it is in the interior of <i>s</i> .
<i>bool</i>	<i>s.collinear_has_on(Point_2<Kernel> p)</i>	checks if point <i>p</i> is on segment <i>s</i> . This function is faster than function <i>has_on()</i> . <i>Precondition:</i> <i>p</i> is on the supporting line of <i>s</i> .

Miscellaneous

<i>Bbox_2</i>	<i>s.bbox()</i>	returns a bounding box containing <i>s</i> .
<i>Segment_2<Kernel></i>	<i>s.transform(Aff_transformation_2<Kernel> t)</i>	returns the segment obtained by applying <i>t</i> on the source and the target of <i>s</i> .

See Also

Kernel::Segment_2.....page [414](#)

CGAL::Triangle_2<Kernel>

Definition

An object t of the class *Triangle_2<Kernel>* is a triangle in the two-dimensional Euclidean plane \mathbb{E}^2 . Triangle t is oriented, i.e., its boundary has clockwise or counterclockwise orientation. We call the side to the left of the boundary the positive side and the side to the right of the boundary the negative side.

The boundary of a triangle splits the plane in two open regions, a bounded one and an unbounded one.

Creation

Triangle_2<Kernel> t (*Point_2<Kernel>* p , *Point_2<Kernel>* q , *Point_2<Kernel>* r);

introduces a triangle t with vertices p , q and r .

Operations

bool $t.operator==(t2)$ Test for equality: two triangles are equal, iff there exists a cyclic permutation of the vertices of $t2$, such that they are equal to the vertices of t .

bool $t.operator!=(t2)$ Test for inequality.

Point_2<Kernel> $t.vertex(int i)$ returns the i 'th vertex modulo 3 of t .

Point_2<Kernel> $t.operator[] (int i)$ returns $vertex(i)$.

Predicates

bool $t.is_degenerate()$ triangle t is degenerate, if the vertices are collinear.

Orientation $t.orientation()$ returns the orientation of t .

Oriented_side $t.oriented_side(Point_2<Kernel> p)$
 returns *ON_ORIENTED_BOUNDARY*, or *POSITIVE_SIDE*, or the constant *ON_NEGATIVE_SIDE*, determined by the position of point p .
Precondition: t is not degenerate.

Bounded_side $t.bounded_side(Point_2<Kernel> p)$
 returns the constant *ON_BOUNDARY*, *ON_BOUNDED_SIDE*, or else *ON_UNBOUNDED_SIDE*, depending on where point p is.
Precondition: t is not degenerate.

For convenience we provide the following boolean functions:

<i>bool</i>	<i>t.has_on_positive_side(Point_2<Kernel> p)</i>
<i>bool</i>	<i>t.has_on_negative_side(Point_2<Kernel> p)</i>
<i>bool</i>	<i>t.has_on_boundary(Point_2<Kernel> p)</i>
<i>bool</i>	<i>t.has_on_bounded_side(Point_2<Kernel> p)</i>
<i>bool</i>	<i>t.has_on_unbounded_side(Point_2<Kernel> p)</i>

Precondition: *t* is not degenerate.

Miscellaneous

<i>Triangle_2<Kernel></i>	<i>t.opposite()</i>	returns a triangle where the boundary is oriented the other way round (this flips the positive and the negative side, but not the bounded and unbounded side).
<i>Kernel::FT</i>	<i>t.area()</i>	returns the signed area of <i>t</i> .
<i>Bbox_2</i>	<i>t.bbox()</i>	returns a bounding box containing <i>t</i> .
<i>Triangle_2<Kernel></i>	<i>t.transform(Aff_transformation_2<Kernel> at)</i>	returns the triangle obtained by applying <i>at</i> on the three vertices of <i>t</i> .

CGAL::Vector_2<Kernel>

Definition

An object of the class *Vector_2<Kernel>* is a vector in the two-dimensional vector space \mathbb{R}^2 . Geometrically spoken, a vector is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2 .

CGAL defines a symbolic constant *NULL_VECTOR*. We will explicitly state where you can pass this constant as an argument instead of a vector initialized with zeros.

Creation

Vector_2<Kernel> *v*(*Point_2<Kernel>* *a*, *Point_2<Kernel>* *b*);

introduces the vector $b - a$.

Vector_2<Kernel> *v*(*Segment_2<Kernel>* *s*);

introduces the vector $s.target() - s.source()$.

Vector_2<Kernel> *v*(*Ray_2<Kernel>* *r*);

introduces the vector having the same direction as *r*.

Vector_2<Kernel> *v*(*Line_2<Kernel>* *l*);

introduces the vector having the same direction as *l*.

Vector_2<Kernel> *v*(*Null_vector* *NULL_VECTOR*);

introduces a null vector *v*.

Vector_2<Kernel> *v*(*Kernel::RT* *hx*, *Kernel::RT* *hy*, *Kernel::RT* *hw* = *RT*(1));

introduces a vector *v* initialized to $(hx/hw, hy/hw)$.
Precondition: $hw \neq 0$

Operations

<i>bool</i>	<i>v.operator==(w)</i>	Test for equality: two vectors are equal, iff their <i>x</i> and <i>y</i> coordinates are equal. You can compare a vector with the <i>NULL_VECTOR</i> .
-------------	-------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------

<i>bool</i>	<i>v.operator!=(w)</i>	Test for inequality. You can compare a vector with the <i>NULL_VECTOR</i> .
-------------	-------------------------	-----------------------------------------------------------------------------

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

<i>Kernel::RT</i>	<i>v.hx()</i>	returns the homogeneous <i>x</i> coordinate.
<i>Kernel::RT</i>	<i>v.hy()</i>	returns the homogeneous <i>y</i> coordinate.

<i>Kernel::RT</i>	<i>v.hw()</i>	returns the homogenizing coordinate.
-------------------	---------------	--------------------------------------

Note that you do not lose information with the homogeneous representation, because the `FieldNumberType` is a quotient.

<i>Kernel::FT</i>	<i>v.x()</i>	returns the x -coordinate of v , that is hx/hw .
<i>Kernel::FT</i>	<i>v.y()</i>	returns the y -coordinate of v , that is hy/hw .

The following operations are for convenience and for compatibility with higher dimensional vectors. Again they come in a Cartesian and homogeneous flavor.

<i>Kernel::RT</i>	<i>v.homogeneous(int i)</i>	returns the i 'th homogeneous coordinate of v , starting with 0.
-------------------	-------------------------------	----------------------------------------------------------------------

Precondition: $0 \leq i \leq 2$.

<i>Kernel::FT</i>	<i>v.cartesian(int i)</i>	returns the i 'th Cartesian coordinate of v , starting at 0.
-------------------	-----------------------------	------------------------------------------------------------------

Precondition: $0 \leq i \leq 1$.

<i>Kernel::FT</i>	<i>v.operator[] (int i)</i>	returns <i>cartesian(i)</i> .
-------------------	-------------------------------	-------------------------------

Precondition: $0 \leq i \leq 1$.

<i>int</i>	<i>v.dimension()</i>	returns the dimension (the constant 2).
------------	----------------------	-----------------------------------------

<i>Direction_2<Kernel></i>	<i>v.direction()</i>	returns the direction which passes through v .
----------------------------------	----------------------	--------------------------------------------------

<i>Vector_2<Kernel></i>	<i>v.transform(Aff_transformation_2<Kernel> t)</i>	
-------------------------------	------------------------------------------------------------	--

returns the vector obtained by applying t on v .

<i>Vector_2<Kernel></i>	<i>v.perpendicular(Orientation o)</i>	
-------------------------------	-----------------------------------------	--

returns the vector perpendicular to v in clockwise or counterclockwise orientation.

Operators

The following operations can be applied to vectors:

<i>Vector_2<Kernel></i>	<i>v.operator+(w)</i>	Addition.
-------------------------------	-------------------------	-----------

<i>Vector_2<Kernel></i>	<i>v.operator-(w)</i>	Subtraction.
-------------------------------	-------------------------	--------------

<i>Vector_2<Kernel></i>	<i>v.operator-()</i>	returns the opposite vector.
-------------------------------	----------------------	------------------------------

<i>Kernel::FT</i>	<i>v.operator*(w)</i>	returns the scalar product (= inner product) of the two vectors.
-------------------	-------------------------	------------------------------------------------------------------

<i>Vector_2<Kernel></i>	<i>operator*(v, Kernel::RT s)</i>	
-------------------------------	-------------------------------------	--

Multiplication with a scalar from the right.

<i>Vector_2<Kernel></i>	<i>operator*(v, Kernel::FT s)</i>	
		Multiplication with a scalar from the right.

<i>Vector_2<Kernel></i>	<i>operator*(Kernel::RT s, v)</i>	
		Multiplication with a scalar from the left.

<i>Vector_2<Kernel></i>	<i>operator*(Kernel::FT s, v)</i>	
		Multiplication with a scalar from the left.

<i>Vector_2<Kernel></i>	<i>v.operator/(Kernel::RT s)</i>	
		Division by a scalar.

2.10.2 Three-dimensional Objects

CGAL::Bbox_3

```
#include <CGAL/Bbox_3.h>
```

Definition

An object b of the class *Bbox_3* is a bounding box in the three-dimensional Euclidean space \mathbb{E}^3 .

Creation

```
Bbox_3 b( double x_min, double y_min, double z_min, double x_max, double y_max, double z_max);
```

introduces a bounding box b with lexicographically smallest corner point at $(x_{min}, y_{min}, z_{min})$ lexicographically largest corner point at $(x_{max}, y_{max}, z_{max})$.

Operations

<i>double</i>	<i>b.xmin()</i>
<i>double</i>	<i>b.ymin()</i>
<i>double</i>	<i>b.zmin()</i>
<i>double</i>	<i>b.xmax()</i>
<i>double</i>	<i>b.ymax()</i>
<i>double</i>	<i>b.zmax()</i>

<i>Bbox_3</i>	<i>b.operator+(c)</i>	returns a bounding box of b and c .
---------------	-------------------------	-----------------------------------------

CGAL::Aff_transformation_3<Kernel>

Definition

The class *Aff_transformation_3<Kernel>* represents three-dimensional affine transformations. The general form of an affine transformation is based on a homogeneous representation of points. Thereby all transformations can be realized by matrix multiplication.

Multiplying the transformation matrix by a scalar does not change the represented transformation. Therefore, any transformation represented by a matrix with rational entries can be represented by a transformation matrix with integer entries as well. (Multiply the matrix with the common denominator of the rational entries.) Hence, it is sufficient to use the number type *Kernel::RT* to represent the entries of the transformation matrix.

CGAL offers several specialized affine transformations. Different constructors are provided to create them. They are parameterized with a symbolic name to denote the transformation type, followed by additional parameters. The symbolic name tags solve ambiguities in the function overloading and they make the code more readable, i.e., what type of transformation is created.

In three-dimensional space we have a 4×4 matrix $(m_{ij})_{i,j=0\dots 3}$. Entries m_{30} , m_{31} , and m_{32} are always zero and therefore do not appear in the constructors.

Creation

```
Aff_transformation_3<Kernel> t( Identity_transformation);
```

introduces an identity transformation.

```
Aff_transformation_3<Kernel> t( const Translation, Vector_3<Kernel> v);
```

introduces a translation by a vector v .

```
Aff_transformation_3<Kernel> t( const Scaling, Kernel::RT s, Kernel::RT hw = RT(1));
```

introduces a scaling by a scale factor s/hw .

```
Aff_transformation_3<Kernel> t( Kernel::RT m00,
                               Kernel::RT m01,
                               Kernel::RT m02,
                               Kernel::RT m03,
                               Kernel::RT m10,
                               Kernel::RT m11,
                               Kernel::RT m12,
                               Kernel::RT m13,
                               Kernel::RT m20,
                               Kernel::RT m21,
                               Kernel::RT m22,
                               Kernel::RT m23,
```

$$\text{Kernel}::RT\ hw = RT(1)$$

introduces a general affine transformation of the matrix form $\begin{pmatrix} m_{00} & m_{01} & m_{02} & m_{03} \\ m_{10} & m_{11} & m_{12} & m_{13} \\ m_{20} & m_{21} & m_{22} & m_{23} \\ 0 & 0 & 0 & hw \end{pmatrix}$. The part $\frac{1}{hw}$ $\begin{pmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{pmatrix}$ defines the scaling and rotational part of the transformation, while the vector $\frac{1}{hw} \begin{pmatrix} m_{03} \\ m_{13} \\ m_{23} \end{pmatrix}$ contains the translational part.

```
Aff_transformation_3<Kernel> t( Kernel::RT m00,
                                Kernel::RT m01,
                                Kernel::RT m02,
                                Kernel::RT m10,
                                Kernel::RT m11,
                                Kernel::RT m12,
                                Kernel::RT m20,
                                Kernel::RT m21,
                                Kernel::RT m22,
                                Kernel::RT hw = RT(1))
```

introduces a general linear transformation of the matrix form $\begin{pmatrix} m_{00} & m_{01} & m_{02} & 0 \\ m_{10} & m_{11} & m_{12} & 0 \\ m_{20} & m_{21} & m_{22} & 0 \\ 0 & 0 & 0 & hw \end{pmatrix}$, i.e. an affine transformation without translational part.

Operations

Each class *Class_3<Kernel>* representing a geometric object in 3D has a member function:

```
Class_3<Kernel> transform(Aff_transformation_3<Kernel> t).
```

The transformation classes provide a member function *transform()* for points, vectors, directions, and planes:

```
Point_3<Kernel>          t.transform( Point_3<Kernel> p)
Vector_3<Kernel>        t.transform( Vector_3<Kernel> p)
Direction_3<Kernel>     t.transform( Direction_3<Kernel> p)
Plane_3<Kernel>         t.transform( Plane_3<Kernel> p)
```

CGAL provides four function operators for these member functions:

```
Point_3<Kernel>          t.operator()( Point_3<Kernel> p)
Vector_3<Kernel>        t.operator()( Vector_3<Kernel> p)
Direction_3<Kernel>     t.operator()( Direction_3<Kernel> p)
Plane_3<Kernel>         t.operator()( Plane_3<Kernel> p)
```

Aff_transformation_3<Kernel>

t.operator(s)* composes two affine transformations.

Aff_transformation_3<Kernel>

t.inverse() gives the inverse transformation.

bool *t.is_even()* returns *true*, if the transformation is not reflecting, i.e. the determinant of the involved linear transformation is non-negative.

bool *t.is_odd()* returns *true*, if the transformation is reflecting.

The matrix entries of a matrix representation of a *Aff_transformation_3<Kernel>* can be accessed through the following member functions:

Kernel::FT *t.cartesian(int i, int j)*
Kernel::FT *t.m(int i, int j)* returns entry m_{ij} in a matrix representation in which m_{33} is 1.

Kernel::RT *t.homogeneous(int i, int j)*
Kernel::RT *t.hm(int i, int j)* returns entry m_{ij} in some fixed matrix representation.

For affine transformations no I/O operators are defined.

CGAL::Direction_3<Kernel>

Definition

An object of the class *Direction_3<Kernel>* is a vector in the three-dimensional vector space \mathbb{R}^3 where we forget about their length. They can be viewed as unit vectors, although there is no normalization internally, since this is error prone. Directions are used whenever the length of a vector does not matter. They also characterize a set of parallel lines that have the same orientation or the direction normal to parallel planes that have the same orientation. For example, you can ask for the direction orthogonal to an oriented plane, or the direction of an oriented line.

Creation

<i>Direction_3<Kernel></i> <i>d</i> (<i>Vector_3<Kernel></i> <i>v</i>);	introduces a direction <i>d</i> initialised with the direction of vector <i>v</i> .
<i>Direction_3<Kernel></i> <i>d</i> (<i>Line_3<Kernel></i> <i>l</i>);	introduces the direction <i>d</i> of line <i>l</i> .
<i>Direction_3<Kernel></i> <i>d</i> (<i>Ray_3<Kernel></i> <i>r</i>);	introduces the direction <i>d</i> of ray <i>r</i> .
<i>Direction_3<Kernel></i> <i>d</i> (<i>Segment_3<Kernel></i> <i>s</i>);	introduces the direction <i>d</i> of segment <i>s</i> .
<i>Direction_3<Kernel></i> <i>d</i> (<i>Kernel::RT</i> <i>x</i> , <i>Kernel::RT</i> <i>y</i> , <i>Kernel::RT</i> <i>z</i>);	introduces a direction <i>d</i> initialised with the direction from the origin to the point with Cartesian coordinates (<i>x</i> , <i>y</i> , <i>z</i>).

Operations

<i>Kernel::RT</i>	<i>d</i> .delta(int <i>i</i>)	returns values, such that <i>d</i> == <i>Direction_3<Kernel></i> (delta(0),delta(1),delta(2)). Precondition: : 0 ≤ <i>i</i> ≤ 2.
<i>Kernel::RT</i>	<i>d</i> .dx()	returns delta(0).
<i>Kernel::RT</i>	<i>d</i> .dy()	returns delta(1).
<i>Kernel::RT</i>	<i>d</i> .dz()	returns delta(2).
bool	<i>d</i> .operator==(<i>e</i>)	Test for equality.
bool	<i>d</i> .operator!=(<i>e</i>)	Test for inequality.
<i>Direction_3<Kernel></i>	<i>d</i> .operator-()	The direction opposite to <i>d</i> .
<i>Vector_3<Kernel></i>	<i>d</i> .vector()	returns a vector that has the same direction as <i>d</i> .
<i>Direction_3<Kernel></i>	<i>d</i> .transform(<i>Aff_transformation_3<Kernel></i> <i>t</i>)	returns the direction obtained by applying <i>t</i> on <i>d</i> .

Kernel::Direction_3 page [352](#)

CGAL::Iso_cuboid_3<Kernel>

Definition

An object s of the data type *Iso_cuboid_3<Kernel>* is a cuboid in the Euclidean space \mathbb{E}^3 with edges parallel to the x , y and z axis of the coordinate system.

Although they are represented in a canonical form by only two vertices, namely the lexicographically smallest and largest vertex with respect to Cartesian xyz coordinates, we provide functions for “accessing” the other vertices as well.

Iso-oriented cuboids and bounding boxes are quite similar. The difference however is that bounding boxes have always double coordinates, whereas the coordinate type of an iso-oriented cuboid is chosen by the user.

Creation

Iso_cuboid_3<Kernel> c (*Point_3<Kernel>* p , *Point_3<Kernel>* q);

introduces an iso-oriented cuboid c with diagonal opposite vertices p and q . Note that the object is brought in the canonical form.

Iso_cuboid_3<Kernel> c (*Point_3<Kernel>* $left$,
Point_3<Kernel> $right$,
Point_3<Kernel> $bottom$,
Point_3<Kernel> top ,
Point_3<Kernel> far ,
Point_3<Kernel> $close$)

introduces an iso-oriented cuboid c whose minimal x coordinate is the one of $left$, the maximal x coordinate is the one of $right$, the minimal y coordinate is the one of $bottom$, the maximal y coordinate is the one of top , the minimal z coordinate is the one of far , the maximal z coordinate is the one of $close$.

Iso_cuboid_3<Kernel> c (*Kernel::RT* min_hx ,
Kernel::RT min_hy ,
Kernel::RT min_hz ,
Kernel::RT max_hx ,
Kernel::RT max_hy ,
Kernel::RT max_hz ,
Kernel::RT $hw = RT(1)$)

introduces an iso-oriented cuboid c with diagonal opposite vertices $(min_hx/hw, min_hy/hw, min_hz/hw)$ and $(max_hx/hw, max_hy/hw, max_hz/hw)$.

Precondition: $hw \neq 0$.

Operations

<i>bool</i>	<i>c.operator==(c2)</i>	Test for equality: two iso-oriented cuboid are equal, iff their lower left and their upper right vertices are equal.
<i>bool</i>	<i>c.operator!=(c2)</i>	Test for inequality.
<i>Point_3<Kernel></i>	<i>c.vertex(int i)</i>	returns the i'th vertex modulo 8 of <i>c</i> . starting with the lower left vertex.
<i>Point_3<Kernel></i>	<i>c.operator[] (int i)</i>	returns <i>vertex(i)</i> , as indicated in the figure below:

<i>Point_3<Kernel></i>	<i>c.min()</i>	returns the smallest vertex of <i>c</i> (= <i>vertex(0)</i>).
<i>Point_3<Kernel></i>	<i>c.max()</i>	returns the largest vertex of <i>c</i> (= <i>vertex(7)</i>).
<i>Kernel::FT</i>	<i>c.xmin()</i>	returns smallest Cartesian <i>x</i> -coordinate in <i>c</i> .
<i>Kernel::FT</i>	<i>c.ymin()</i>	returns smallest Cartesian <i>y</i> -coordinate in <i>c</i> .
<i>Kernel::FT</i>	<i>c.zmin()</i>	returns smallest Cartesian <i>z</i> -coordinate in <i>c</i> .
<i>Kernel::FT</i>	<i>c.xmax()</i>	returns largest Cartesian <i>x</i> -coordinate in <i>c</i> .
<i>Kernel::FT</i>	<i>c.ymax()</i>	returns largest Cartesian <i>y</i> -coordinate in <i>c</i> .
<i>Kernel::FT</i>	<i>c.zmax()</i>	returns largest Cartesian <i>z</i> -coordinate in <i>c</i> .
<i>Kernel::FT</i>	<i>c.min_coord(int i)</i>	returns <i>i</i> -th Cartesian coordinate of the smallest vertex of <i>c</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>Kernel::FT</i>	<i>c.max_coord(int i)</i>	returns <i>i</i> -th Cartesian coordinate of the largest vertex of <i>c</i> . <i>Precondition:</i> $0 \leq i \leq 2$.

Predicates

<i>bool</i>	<i>c.is_degenerate()</i>	<i>c</i> is degenerate, if all vertices are collinear.
<i>Bounded_side</i>	<i>c.bounded_side(Point_3<Kernel> p)</i>	returns either <i>ON_UNBOUNDED_SIDE</i> , <i>ON_BOUNDED_SIDE</i> , or the constant <i>ON_BOUNDARY</i> , depending on where point <i>p</i> is.
<i>bool</i>	<i>c.has_on_boundary(Point_3<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_bounded_side(Point_3<Kernel> p)</i>	

bool *c.has_on_unbounded_side(Point_3<Kernel> p)*

Miscellaneous

Kernel::FT *c.volume()* returns the volume of *c*.

Bbox *c.bbox()* returns a bounding box containing *c*.

Iso_cuboid_3<Kernel> *c.transform(Aff_transformation_3<Kernel> t)*

returns the iso-oriented cuboid obtained by applying *t* on the smallest and the largest of *c*.

Precondition: The angle at a rotation must be a multiple of $\pi/2$, otherwise the resulting cuboid does not have the same size. Note that rotating about an arbitrary angle can even result in a degenerate iso-oriented cuboid.

See Also

Kernel::IsoCuboid_3 page [381](#)

CGAL::Line_3<Kernel>

Definition

An object l of the data type $Line_3<Kernel>$ is a directed straight line in the three-dimensional Euclidean space \mathbb{E}^3 .

Creation

$Line_3<Kernel> \ l(Point_3<Kernel> \ p, Point_3<Kernel> \ q);$

introduces a line l passing through the points p and q .
Line l is directed from p to q .

$Line_3<Kernel> \ l(Point_3<Kernel> \ p, Direction_3<Kernel> \ d);$

introduces a line l passing through point p with direction d .

$Line_3<Kernel> \ l(Point_3<Kernel> \ p, Vector_3<Kernel> \ v);$

introduces a line l passing through point p and oriented by v .

$Line_3<Kernel> \ l(Segment_3<Kernel> \ s);$

returns the line supporting the segment s , oriented from source to target.

$Line_3<Kernel> \ l(Ray_3<Kernel> \ r);$

returns the line supporting the ray r , with the same orientation.

Operations

$bool \quad \quad \quad l.operator==(h)$ Test for equality: two lines are equal, iff they have a non empty intersection and the same direction.

$bool \quad \quad \quad l.operator!=(h)$ Test for inequality.

$Point_3<Kernel> \quad \quad l.projection(Point_3<Kernel> \ p)$
returns the orthogonal projection of p on l .

$Point_3<Kernel> \quad \quad l.point(int \ i)$ returns an arbitrary point on l . It holds $point(i) = point(j)$, iff $i=j$.

Predicates

<i>bool</i>	<i>lis_degenerate()</i>	returns <i>true</i> iff line <i>l</i> is degenerated to a point.
-------------	-------------------------	------------------------------------------------------------------

bool *l.has_on(Point_3<Kernel> p)*
returns *true* iff *p* lies on *l*.

Miscellaneous

Plane_3<Kernel> *l.perpendicular_plane(Point_3<Kernel> p)*

returns the plane perpendicular to *l* passing through *p*.

Line_3<Kernel> *l.opposite()* returns the line with opposite direction.

Vector_3<Kernel> *l.to_vector()* returns a vector having the same direction as *l*.

Direction_3<Kernel> *l.direction()* returns the direction of *l*.

<i>Line_3<Kernel></i>	<i>l.transform(Aff_transformation_3<Kernel> t)</i>	
		returns the line obtained by applying <i>t</i> on a point on <i>l</i> and the direction of <i>l</i> .

See Also

Kernel:Line_3 page 400

CGAL::Plane_3<Kernel>

Definition

An object h of the data type $\text{Plane}_3<\text{Kernel}>$ is an oriented plane in the three-dimensional Euclidean space \mathbb{E}^3 . It is defined by the set of points with Cartesian coordinates (x, y, z) that satisfy the plane equation

$$h: ax + by + cz + d = 0.$$

The plane splits \mathbb{E}^3 in a *positive* and a *negative side*. A point p with Cartesian coordinates (px, py, pz) is on the positive side of h , iff $apx + bpy + cpz + d > 0$. It is on the negative side, iff $apx + bpy + cpz + d < 0$.

Creation

$\text{Plane}_3<\text{Kernel}> \ h(\text{Kernel}::\text{RT } a, \text{Kernel}::\text{RT } b, \text{Kernel}::\text{RT } c, \text{Kernel}::\text{RT } d);$

creates a plane h defined by the equation $apx + bpy + cpz + d = 0$. Notice that h is degenerate if $a = b = c$.

$\text{Plane}_3<\text{Kernel}> \ h(\text{Point}_3<\text{Kernel}> \ p, \text{Point}_3<\text{Kernel}> \ q, \text{Point}_3<\text{Kernel}> \ r);$

creates a plane h passing through the points p , q and r . The plane is oriented such that p , q and r are oriented in a positive sense (that is counterclockwise) when seen from the positive side of h . Notice that h is degenerate if the points are collinear.

$\text{Plane}_3<\text{Kernel}> \ h(\text{Point}_3<\text{Kernel}> \ p, \text{Vector}_3<\text{Kernel}> \ v);$

introduces a plane h that passes through point p and that is orthogonal to v .

$\text{Plane}_3<\text{Kernel}> \ h(\text{Point}_3<\text{Kernel}> \ p, \text{Direction}_3<\text{Kernel}> \ d);$

introduces a plane h that passes through point p and that has as an orthogonal direction equal to d .

$\text{Plane}_3<\text{Kernel}> \ h(\text{Line}_3<\text{Kernel}> \ l, \text{Point}_3<\text{Kernel}> \ p);$

introduces a plane h that is defined through the three points $l.\text{point}(0)$, $l.\text{point}(1)$ and p .

$\text{Plane}_3<\text{Kernel}> \ h(\text{Ray}_3<\text{Kernel}> \ r, \text{Point}_3<\text{Kernel}> \ p);$

introduces a plane h that is defined through the three points $r.\text{point}(0)$, $r.\text{point}(1)$ and p .

Plane_3<Kernel> h(Segment_3<Kernel> s, Point_3<Kernel> p);

introduces a plane *h* that is defined through the three points *s.source()*, *s.target()* and *p*.

Operations

bool *h.operator==(h2)* Test for equality: two planes are equal, iff they have a non empty intersection and the same orientation.

bool *h.operator!=(h2)* Test for inequality.

Kernel::RT *h.a()* returns the first coefficient of *h*.
Kernel::RT *h.b()* returns the second coefficient of *h*.
Kernel::RT *h.c()* returns the third coefficient of *h*.
Kernel::RT *h.d()* returns the fourth coefficient of *h*.

Line_3<Kernel> *h.perpendicular_line(Point_3<Kernel> p)*
 returns the line that is perpendicular to *h* and that passes through point *p*. The line is oriented from the negative to the positive side of *h*.

Point_3<Kernel> *h.projection(Point_3<Kernel> p)*
 returns the orthogonal projection of *p* on *h*.

Plane_3<Kernel> *h.opposite()* returns the plane with opposite orientation.

Point_3<Kernel> *h.point()* returns an arbitrary point on *h*.

Vector_3<Kernel> *h.orthogonal_vector()*
 returns a vector that is orthogonal to *h* and that is directed to the positive side of *h*.

Direction_3<Kernel> *h.orthogonal_direction()*
 returns the direction that is orthogonal to *h* and that is directed to the positive side of *h*.

Vector_3<Kernel> *h.base1()* returns a vector orthogonal to *orthogonal_vector()*.

Vector_3<Kernel> *h.base2()* returns a vector that is both orthogonal to *base1()*, and to *orthogonal_vector()*, and such that the result of *orientation(point(), point() + base1(), point()+base2(), point() + orthogonal_vector())* is positive.

2D Conversion

The following functions provide conversion between a plane and CGAL's two-dimensional space. The transformation is affine, but not necessarily an isometry. This means, the transformation preserves combinatorics, but not distances.

Point_2<Kernel> *h.to_2d(Point_3<Kernel> p)*

returns the image point of the projection of *p* under an affine transformation, which maps *h* onto the *xy*-plane, with the *z*-coordinate removed.

Point_3<Kernel> *h.to_3d(Point_2<Kernel> p)*

returns a point *q*, such that *to_2d(to_3d(p))* is equal to *p*.

Predicates

Oriented_side *h.oriented_side(Point_3<Kernel> p)*

returns either *ON_ORIENTED_BOUNDARY*, or the constant *ON_POSITIVE_SIDE*, or the constant *ON_NEGATIVE_SIDE*, determined by the position of *p* relative to the oriented plane *h*.

For convenience we provide the following boolean functions:

bool *h.has_on(Point_3<Kernel> p)*
bool *h.has_on_positive_side(Point_3<Kernel> p)*
bool *h.has_on_negative_side(Point_3<Kernel> p)*

bool *h.has_on(Line_3<Kernel> l)*

bool *h.is_degenerate()* Plane *h* is degenerate, if the coefficients *a*, *b*, and *c* of the plane equation are zero.

Miscellaneous

Plane_3<Kernel> *h.transform(Aff_transformation_3<Kernel> t)*

returns the plane obtained by applying *t* on a point of *h* and the orthogonal direction of *h*.

Kernel::Plane_3.....page [407](#)

CGAL::Point_3<Kernel>

Definition

An object of the class *Point_3<Kernel>* is a point in the three-dimensional Euclidean space \mathbb{E}^3 .

Remember that *Kernel::RT* and *Kernel::FT* denote a RingNumberType and a FieldNumberType, respectively. For the kernel model *Cartesian<T>*, the two types are the same. For the kernel model *Homogeneous<T>*, *Kernel::RT* is equal to *T*, and *Kernel::FT* is equal to *Quotient<T>*.

Types

Point_3<Kernel>::Cartesian_const_iterator

An iterator for enumerating the Cartesian coordinates of a point.

Creation

Point_3<Kernel> p(Origin ORIGIN);

introduces a point with Cartesian coordinates(0,0,0).

Point_3<Kernel> p(Kernel::RT hx, Kernel::RT hy, Kernel::RT hz, Kernel::RT hw = RT(1));

introduces a point *p* initialized to $(hx/hw, hy/hw, hz/hw)$.
Precondition: $hw \neq 0$.

Operations

bool p.operator==(q)

Test for equality: Two points are equal, iff their *x*, *y* and *z* coordinates are equal.

bool p.operator!=(q)

Test for inequality.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT p.hx()

returns the homogeneous *x* coordinate.

<i>Kernel::RT</i>	<i>p.hy()</i>	
		returns the homogeneous y coordinate.
<i>Kernel::RT</i>	<i>p.hz()</i>	
		returns the homogeneous z coordinate.
<i>Kernel::RT</i>	<i>p.hw()</i>	
		returns the homogenizing coordinate.

Note that you do not lose information with the homogeneous representation, because the `FieldNumberType` is a quotient.

<i>Kernel::FT</i>	<i>p.x()</i>	returns the Cartesian x coordinate, that is hx/hw .
<i>Kernel::FT</i>	<i>p.y()</i>	returns the Cartesian y coordinate, that is hy/hw .
<i>Kernel::FT</i>	<i>p.z()</i>	returns the Cartesian z coordinate, that is hz/hw .

The following operations are for convenience and for compatibility with code for higher dimensional points. Again they come in a Cartesian and in a homogeneous flavor.

<i>Kernel::RT</i>	<i>p.homogeneous(int i)</i>	
		returns the i 'th homogeneous coordinate of p , starting with 0. <i>Precondition:</i> $0 \leq i \leq 3$.

<i>Kernel::FT</i>	<i>p.cartesian(int i)</i>	
		returns the i 'th Cartesian coordinate of p , starting with 0. <i>Precondition:</i> $0 \leq i \leq 2$.

<i>Kernel::FT</i>	<i>p.operator[](int i)</i>	
		returns <i>cartesian(i)</i> . <i>Precondition:</i> $0 \leq i \leq 2$.

<i>Cartesian_const_iterator</i>	<i>p.cartesian_begin()</i>	
		returns an iterator to the Cartesian coordinates of p , starting with the 0th coordinate.

<i>Cartesian_const_iterator</i>	<i>p.cartesian_end()</i>	
		returns an off the end iterator to the Cartesian coordinates of p .

<i>int</i>	<i>p.dimension()</i>	
		returns the dimension (the constant 3).

Bbox_3 *p.bbox()*
returns a bounding box containing *p*.

Point_3<Kernel> *p.transform(Aff_transformation_3<Kernel> t)*
returns the point obtained by applying *t* on *p*.

Operators

The following operations can be applied on points:

bool *operator<(p, q)*
returns true iff *p* is lexicographically smaller than *q* (the lexicographical order being defined on the Cartesian coordinates).

bool *operator>(p, q)*
returns true iff *p* is lexicographically greater than *q*.

bool *operator<=(p, q)*
returns true iff *p* is lexicographically smaller or equal to *q*.

bool *operator>=(p, q)*
returns true iff *p* is lexicographically greater or equal to *q*.

Vector_3<Kernel> *operator-(p, q)*
returns the difference vector between *q* and *p*. You can substitute *ORIGIN* for either *p* or *q*, but not for both.

Point_3<Kernel> *operator+(p, Vector_3<Kernel> v)*
returns the point obtained by translating *p* by the vector *v*.

Point_3<Kernel> *operator-(p, Vector_3<Kernel> v)*
returns the point obtained by translating *p* by the vector *-v*.

Kernel::Point_3.....page [410](#)

CGAL::Ray_3<Kernel>

Definition

An object r of the data type $\text{Ray}_3<\text{Kernel}>$ is a directed straight ray in the three-dimensional Euclidean space \mathbb{E}^3 . It starts in a point called the *source* of r and it goes to infinity.

Creation

$\text{Ray}_3<\text{Kernel}> \ r(\text{Point}_3<\text{Kernel}> \ p, \text{Point}_3<\text{Kernel}> \ q);$

introduces a ray r with source p and passing through point q .

$\text{Ray}_3<\text{Kernel}> \ r(\text{Point}_3<\text{Kernel}> \ p, \text{Direction}_3<\text{Kernel}> \ d);$

introduces a ray r with source p and with direction d .

$\text{Ray}_3<\text{Kernel}> \ r(\text{Point}_3<\text{Kernel}> \ p, \text{Vector}_3<\text{Kernel}> \ v);$

introduces a ray r with source p and with a direction given by v .

$\text{Ray}_3<\text{Kernel}> \ r(\text{Point}_3<\text{Kernel}> \ p, \text{Line}_3<\text{Kernel}> \ l);$

introduces a ray r starting at source p with the same direction as l .

Operations

<i>bool</i>	$r.operator==(h)$	Test for equality: two rays are equal, iff they have the same source and the same direction.
<i>bool</i>	$r.operator!=(h)$	Test for inequality.
$\text{Point}_3<\text{Kernel}>$	$r.source()$	returns the source of r
$\text{Point}_3<\text{Kernel}>$	$r.point(\text{int } i)$	returns a point on r . $point(0)$ is the source. $point(i)$, with $i > 0$, is different from the source. <i>Precondition:</i> $i \geq 0$.
$\text{Direction}_3<\text{Kernel}>$	$r.direction()$	returns the direction of r .
$\text{Vector}_3<\text{Kernel}>$	$r.to_vector()$	returns a vector giving the direction of r .

<i>Line_3<Kernel></i>	<i>r.supporting_line()</i>	returns the line supporting <i>r</i> which has the same direction.
<i>Ray_3<Kernel></i>	<i>r.opposite()</i>	returns the ray with the same source and the opposite direction.
<i>bool</i>	<i>r.is_degenerate()</i>	ray <i>r</i> is degenerate, if the source and the second defining point fall together (that is if the direction is degenerate).
<i>bool</i>	<i>r.has_on(Point_3<Kernel> p)</i>	A point is on <i>r</i> , iff it is equal to the source of <i>r</i> , or if it is in the interior of <i>r</i> .
<i>Ray_3<Kernel></i>	<i>r.transform(Aff_transformation_3<Kernel> t)</i>	returns the ray obtained by applying <i>t</i> on the source and on the direction of <i>r</i> .

See Also

Kernel::Ray_3 page [413](#)

CGAL::Segment_3<Kernel>

Definition

An object s of the data type $\text{Segment}_3<\text{Kernel}>$ is a directed straight line segment in the three-dimensional Euclidean space \mathbb{E}^3 , i.e. a straight line segment $[p, q]$ connecting two points $p, q \in \mathbb{R}^3$. The segment is topologically closed, i.e. the end points belong to it. Point p is called the *source* and q is called the *target* of s . The length of s is the Euclidean distance between p and q . Note that there is only a function to compute the square of the length, because otherwise we had to perform a square root operation which is not defined for all number types, which is expensive, and may not be exact.

Creation

$\text{Segment}_3<\text{Kernel}> \ s(\text{Point}_3<\text{Kernel}> \ p, \text{Point}_3<\text{Kernel}> \ q);$

introduces a segment s with source p and target q . It is directed from the source towards the target.

Operations

$bool$	$s.operator==(q)$	Test for equality: Two segments are equal, iff their sources and targets are equal.
$bool$	$s.operator!=(q)$	Test for inequality.
$\text{Point}_3<\text{Kernel}>$	$s.source()$	returns the source of s .
$\text{Point}_3<\text{Kernel}>$	$s.target()$	returns the target of s .
$\text{Point}_3<\text{Kernel}>$	$s.min()$	returns the point of s with smallest coordinate (lexicographically).
$\text{Point}_3<\text{Kernel}>$	$s.max()$	returns the point of s with largest coordinate (lexicographically).
$\text{Point}_3<\text{Kernel}>$	$s.vertex(int\ i)$	returns source or target of s : $vertex(0)$ returns the source, $vertex(1)$ returns the target. The parameter i is taken modulo 2, which gives easy access to the other vertex.
$\text{Point}_3<\text{Kernel}>$	$s.point(int\ i)$	returns $vertex(i)$.
$\text{Point}_3<\text{Kernel}>$	$s.operator[] (int\ i)$	returns $vertex(i)$.
$\text{Kernel}::FT$	$s.squared_length()$	returns the squared length of s .
$\text{Vector}_3<\text{Kernel}>$	$s.to_vector()$	returns the vector $s.target() - s.source()$.
$\text{Direction}_3<\text{Kernel}>$	$s.direction()$	returns the direction from source to target.

<i>Segment_3<Kernel></i>	<i>s.opposite()</i>	returns a segment with source and target interchanged.
<i>Line_3<Kernel></i>	<i>s.supporting_line()</i>	returns the line <i>l</i> passing through <i>s</i> . Line <i>l</i> has the same orientation as segment <i>s</i> , that is from the source to the target of <i>s</i> .
<i>bool</i>	<i>s.is_degenerate()</i>	segment <i>s</i> is degenerate, if source and target fall together.
<i>bool</i>	<i>s.has_on(Point_3<Kernel> p)</i>	A point is on <i>s</i> , iff it is equal to the source or target of <i>s</i> , or if it is in the interior of <i>s</i> .
<i>Bbox_3</i>	<i>s.bbox()</i>	returns a bounding box containing <i>s</i> .
<i>Segment_3<Kernel></i>	<i>s.transform(Aff_transformation_3<Kernel> t)</i>	returns the segment obtained by applying <i>t</i> on the source and the target of <i>s</i> .

Kernel::Segment_3.....page [415](#)

CGAL::Sphere_3<Kernel>

Definition

An object of type *Sphere_3<Kernel>* is a sphere in the three-dimensional Euclidean space \mathbb{E}^3 . The sphere is oriented, i.e. its boundary has clockwise or counterclockwise orientation. The boundary splits \mathbb{E}^3 into a positive and a negative side, where the positive side is to the left of the boundary. The boundary also splits \mathbb{E}^3 into a bounded and an unbounded side. Note that the sphere can be degenerated, i.e. the squared radius may be zero.

Creation

Sphere_3<Kernel> *c*(*Point_3<Kernel>* *center*,
 Kernel::FT *squared_radius*,
 Orientation *orientation* = *COUNTERCLOCKWISE*)

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the sphere with center *center*, squared radius *squared_radius* and orientation *orientation*.

Precondition: *orientation* \neq *COPLANAR*, and furthermore, *squared_radius* \geq 0.

Sphere_3<Kernel> *c*(*Point_3<Kernel>* *p*, *Point_3<Kernel>* *q*, *Point_3<Kernel>* *r*, *Point_3<Kernel>* *s*);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the unique sphere which passes through the points *p*, *q*, *r* and *s*. The orientation of the sphere is the orientation of the point quadruple *p*, *q*, *r*, *s*.

Precondition: *p*, *q*, *r*, and *s* are not collinear.

Sphere_3<Kernel> *c*(*Point_3<Kernel>* *p*,
 Point_3<Kernel> *q*,
 Point_3<Kernel> *r*,
 Orientation *o* = *COUNTERCLOCKWISE*)

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the smallest sphere which passes through the points *p*, *q*, and *r*. The orientation of the sphere is *o*.

Precondition: *o* is not *COPLANAR*.

Sphere_3<Kernel> *c*(*Point_3<Kernel>* *p*, *Point_3<Kernel>* *q*, *Orientation* *o* = *COUNTERCLOCKWISE*);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the smallest sphere which passes through the points *p* and *q*. The orientation of the sphere is *o*.

Precondition: *o* is not *COPLANAR*.

Sphere_3<Kernel> *c*(*Point_3<Kernel>* *center*, *Orientation* *orientation* = *COUNTERCLOCKWISE*);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the sphere with center *center*, squared radius zero and orientation *orientation*.

Precondition: *orientation* \neq *COPLANAR*.

Postcondition: *c.is_degenerate()* = *true*.

Access Functions

<i>Point_3<Kernel></i> <i>Kernel::FT</i> <i>orientation</i>	<i>c.center()</i> <i>c.squared_radius()</i> <i>c.orientation()</i>	returns the center of <i>c</i> . returns the squared radius of <i>c</i> . returns the orientation of <i>c</i> .
<i>bool operator</i>	<i>c.==(sphere2)</i>	returns <i>true</i> , iff <i>c</i> and <i>sphere2</i> are equal, i.e. if they have the same center, same squared radius and same orientation.
<i>bool operator</i>	<i>c.!=(sphere2)</i>	returns <i>true</i> , iff <i>c</i> and <i>sphere2</i> are not equal.

Predicates

<i>bool</i>	<i>c.is_degenerate()</i>	returns <i>true</i> , iff <i>c</i> is degenerate, i.e. if <i>c</i> has squared radius zero.
<i>Oriented_side</i>	<i>c.oriented_side(Point_3<Kernel> p)</i>	returns either the constant <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_POSITIVE_SIDE</i> , or <i>ON_NEGATIVE_SIDE</i> , iff <i>p</i> lies on the boundary, properly on the positive side, or properly on the negative side of <i>c</i> , resp.
<i>Bounded_side</i>	<i>c.bounded_side(Point_3<Kernel> p)</i>	returns <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> , or <i>ON_UNBOUNDED_SIDE</i> iff <i>p</i> lies properly inside, on the boundary, or properly outside of <i>c</i> , resp.
<i>bool</i>	<i>c.has_on_positive_side(Point_3<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_negative_side(Point_3<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_boundary(Point_3<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_bounded_side(Point_3<Kernel> p)</i>	
<i>bool</i>	<i>c.has_on_unbounded_side(Point_3<Kernel> p)</i>	

Miscellaneous

<i>Sphere_3<Kernel></i>	<i>c.opposite()</i>	returns the sphere with the same center and squared radius as <i>c</i> but with opposite orientation.
-------------------------------	---------------------	-------------------------------------------------------------------------------------------------------

<i>Sphere_3<Kernel></i>	<i>c.orthogonal_transform(Aff_transformation_3<Kernel> at)</i>	<p>returns the sphere obtained by applying <i>at</i> on <i>c</i>. <i>Precondition:</i> <i>at</i> is an orthogonal transformation.</p>
-------------------------------	-----------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------

<i>Bbox_3</i>	<i>c.bbox()</i>	returns a bounding box containing <i>c</i> .
---------------	-----------------	----------------------------------------------

Kernel::Sphere_3 page [420](#)

CGAL::Tetrahedron_3<Kernel>

Definition

An object t of the class *Tetrahedron_3<Kernel>* is an oriented tetrahedron in the three-dimensional Euclidean space \mathbb{E}^3 .

It is defined by four vertices p_0, p_1, p_2 and p_3 . The orientation of a tetrahedron is the orientation of its four vertices. That means it is positive when p_3 is on the positive side of the plane defined by p_0, p_1 and p_2 .

The tetrahedron itself splits the space \mathbb{E}_3 in a *positive* and a *negative* side.

The boundary of a tetrahedron splits the space in two open regions, a bounded one and an unbounded one.

Creation

```
Tetrahedron_3<Kernel> t( Point_3<Kernel> p0,
                        Point_3<Kernel> p1,
                        Point_3<Kernel> p2,
                        Point_3<Kernel> p3)
```

introduces a tetrahedron t with vertices p_0, p_1, p_2 and p_3 .

Operations

<i>bool</i>	<i>t.operator==(t2)</i>	Test for equality: two tetrahedra t and $t2$ are equal, iff t and $t2$ have the same orientation and their sets (not sequences) of vertices are equal.
<i>bool</i>	<i>t.operator!=(t2)</i>	Test for inequality.
<i>Point_3<Kernel></i>	<i>t.vertex(int i)</i>	returns the i 'th vertex modulo 4 of t .
<i>Point_3<Kernel></i>	<i>t.operator[](int i)</i>	returns <i>vertex(int i)</i> .

Predicates

<i>bool</i>	<i>t.is_degenerate()</i>	Tetrahedron t is degenerate, if the vertices are coplanar.
<i>Orientation</i>	<i>t.orientation()</i>	
<i>Oriented_side</i>	<i>t.oriented_side(Point_3<Kernel> p)</i>	

Precondition: : t is not degenerate.

Bounded_side *t.bounded_side(Point_3<Kernel> p)*

Precondition: : *t* is not degenerate.

For convenience we provide the following boolean functions:

bool *t.has_on_positive_side(Point_3<Kernel> p)*
bool *t.has_on_negative_side(Point_3<Kernel> p)*
bool *t.has_on_boundary(Point_3<Kernel> p)*
bool *t.has_on_bounded_side(Point_3<Kernel> p)*
bool *t.has_on_unbounded_side(Point_3<Kernel> p)*

Miscellaneous

Kernel::FT *t.volume()* returns the signed volume of *t*.

Bbox_3 *t.bbox()* returns a bounding box containing *t*.

Tetrahedron_3<Kernel> *t.transform(Aff_transformation_3<Kernel> at)*

returns the tetrahedron obtained by applying *at* on the three vertices of *t*.

See Also

Kernel::Tetrahedron_3 page [421](#)

CGAL::Triangle_3<Kernel>

Definition

An object t of the class *Triangle_3<Kernel>* is a triangle in the three-dimensional Euclidean space \mathbb{E}^3 . As the triangle is not a full-dimensional object there is only a test whether a point lies on the triangle or not.

Creation

Triangle_3<Kernel> t (*Point_3<Kernel>* p , *Point_3<Kernel>* q , *Point_3<Kernel>* r);

introduces a triangle t with vertices p , q and r .

Operations

bool $t.operator==(t_2)$ Test for equality: two triangles t and t_2 are equal, iff there exists a cyclic permutation of the vertices of t_2 , such that they are equal to the vertices of t .

bool $t.operator!=(t_2)$ Test for inequality.

Point_3<Kernel> $t.vertex(int\ i)$ returns the i 'th vertex modulo 3 of t .

Point_3<Kernel> $t.operator[](int\ i)$ returns $vertex(int\ i)$.

Plane_3<Kernel> $t.supporting_plane()$ returns the supporting plane of t , with same orientation.

Predicates

bool $t.is_degenerate()$ t is degenerate if its vertices are collinear.

bool $t.has_on(Point_3<Kernel>\ p)$

A point is on t , if it is on a vertex, an edge or the face of t .

Miscellaneous

Kernel::FT $t.squared_area()$ returns a square of the area of t .

Bbox_3 $t.bbox()$ returns a bounding box containing t .

Triangle_3<Kernel> *t.transform(Aff_transformation_3<Kernel> at)*

returns the triangle obtained by applying *at* on the three vertices of *t*.

See Also

Kernel::Triangle_3 page [423](#)

CGAL::Vector_3<Kernel>

Definition

An object of the class *Vector_3<Kernel>* is a vector in the three-dimensional vector space \mathbb{R}^3 . Geometrically spoken a vector is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2 .

CGAL defines a symbolic constant *NULL_VECTOR*. We will explicitly state where you can pass this constant as an argument instead of a vector initialized with zeros.

Creation

Vector_3<Kernel> *v*(*Point_3<Kernel>* *a*, *Point_3<Kernel>* *b*);

introduces the vector $b - a$.

Vector_3<Kernel> *v*(*Segment_3<Kernel>* *s*);

introduces the vector $s.target() - s.source()$.

Vector_3<Kernel> *v*(*Ray_3<Kernel>* *r*);

introduces a vector having the same direction as *r*.

Vector_3<Kernel> *v*(*Line_3<Kernel>* *l*);

introduces a vector having the same direction as *l*.

Vector_3<Kernel> *v*(*Null_vector* *NULL_VECTOR*);

introduces a null vector *v*.

Vector_3<Kernel> *v*(*Kernel::RT* *hx*, *Kernel::RT* *hy*, *Kernel::FT* *hz*, *Kernel::RT* *hw* = *RT(1)*);

introduces a vector *v* initialized to $(hx/hw, hy/hw, hz/hw)$.

Operations

bool

v.operator==(w)

Test for equality: two vectors are equal, iff their *x*, *y* and *z* coordinates are equal. You can compare a vector with the *NULL_VECTOR*.

bool

v.operator!=(w)

Test for inequality. You can compare a vector with the *NULL_VECTOR*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT

v.hx()

returns the homogeneous *x* coordinate.

Kernel::RT

v.hy()

returns the homogeneous *y* coordinate.

Kernel::RT

v.hz()

returns the homogeneous *z* coordinate.

<i>Kernel::RT</i>	<i>v.hw()</i>	returns the homogenizing coordinate.
-------------------	---------------	--------------------------------------

Note that you do not lose information with the homogeneous representation, because the `FieldNumberType` is a quotient.

<i>Kernel::FT</i>	<i>v.x()</i>	returns the x -coordinate of v , that is hx/hw .
<i>Kernel::FT</i>	<i>v.y()</i>	returns the y -coordinate of v , that is hy/hw .
<i>Kernel::FT</i>	<i>v.z()</i>	returns the z coordinate of v , that is hz/hw .

The following operations are for convenience and for compatibility with higher dimensional vectors. Again they come in a Cartesian and homogeneous flavor.

<i>Kernel::RT</i>	<i>v.homogeneous(int i)</i>	returns the i 'th homogeneous coordinate of v , starting with 0. <i>Precondition:</i> $0 \leq i \leq 3$.
-------------------	-------------------------------	------------------------------------------------------------------------------------------------------------------

<i>Kernel::FT</i>	<i>v.cartesian(int i)</i>	returns the i 'th Cartesian coordinate of v , starting at 0. <i>Precondition:</i> $0 \leq i \leq 2$.
-------------------	-----------------------------	--------------------------------------------------------------------------------------------------------------

<i>Kernel::FT</i>	<i>v.operator[] (int i)</i>	returns <i>cartesian</i> (i). <i>Precondition:</i> $0 \leq i \leq 2$.
-------------------	-------------------------------	-------------------------------------------------------------------------------

<i>int</i>	<i>v.dimension()</i>	returns the dimension (the constant 3).
------------	----------------------	-----------------------------------------

<i>Vector_3<Kernel></i>	<i>v.transform(Aff_transformation_3<Kernel> t)</i>	returns the vector obtained by applying t on v .
-------------------------------	------------------------------------------------------------	------------------------------------------------------

<i>Direction_3<Kernel></i>	<i>v.direction()</i>	returns the direction of v .
----------------------------------	----------------------	--------------------------------

Operators

The following operations can be applied on vectors:

<i>Vector_3<Kernel></i>	<i>v.operator+(w)</i>	Addition.
-------------------------------	-------------------------	-----------

<i>Vector_3<Kernel></i>	<i>v.operator-(w)</i>	Subtraction.
-------------------------------	-------------------------	--------------

<i>Vector_3<Kernel></i>	<i>v.operator-()</i>	Returns the opposite vector.
-------------------------------	----------------------	------------------------------

<i>Kernel::FT</i>	<i>v.operator*(w)</i>	returns the scalar product (= inner product) of the two vectors.
-------------------	-------------------------	------------------------------------------------------------------

<i>Vector_3<Kernel></i>	<i>operator*(v, Kernel::RT s)</i>	Multiplication with a scalar from the right.
-------------------------------	-------------------------------------	----------------------------------------------

<i>Vector_3<Kernel></i>	<i>operator*(v, Kernel::FT s)</i>	Multiplication with a scalar from the right.
-------------------------------	-------------------------------------	----------------------------------------------

Vector_3<Kernel> *operator*(Kernel::RT s, v)*
 Multiplication with a scalar from the left.

Vector_3<Kernel> *operator*(Kernel::FT s, v)*
 Multiplication with a scalar from the left.

Vector_3<Kernel> *v.operator/(Kernel::RT s)*
 Division by a scalar.

2.10.3 Polymorphic Objects

CGAL::Object

`#include <CGAL/Object.h>`

Definition

Some functions can return different types of objects. A typical C++ solution to this problem is to derive all possible return types from a common base class, to return a pointer to this class and to perform a dynamic cast on this pointer. The class *Object* provides an abstraction. An object *obj* of the class *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make_object*. This encapsulation mechanism requires the use of *assign* or *object_cast* to use the functionality of the encapsulated class.

Creation

Object obj; introduces an empty object.

Object obj(o); Copy constructor.

Objects of type *Object* are normally created using the global function *make_object*.

Operations

Object& *obj.operator=(o)* Assignment.

bool *obj.is_empty()* returns true, if *obj* does not contain an object.

std::type_info *obj.type()* returns the type information of the contained type, or *typeid(void)* if empty.

Construction of an *Object* storing an object of type *T* can be performed using the *make_object* global function :

template <class T>
Object *make_object(T t)* Creates an object that contains *t*.

Assignment of an object of type *Object* to an object of type *T* can be done using *assign* :

template <class T>
bool *assign(T& c, o)* assigns *o* to *c* if *o* was constructed from an object of type *T*. Returns *true*, if the assignment was possible.

Another possibility to access the encapsulated object is to use *object_cast*, which avoids the default constructor and assignment required by *assign* :

template <class T>

*const T** *object_cast(const * o)*

Returns a pointer to the object of type *T* stored by *o*, if any, otherwise returns *NULL*.

template <class T>

T *object_cast(o)*

Returns a copy of the object of type *T* stored by *o*, if any, otherwise throws an exception of type *Bad_object_cast*.

Example

In the following example, the object class is used as return value for the intersection computation, as there are possibly different return values.

```
{
    typedef Cartesian<double>    K;
    typedef K::Point_2          Point_2;
    typedef K::Segment_2         Segment_2;

    Point_2 point;
    Segment_2 segment, segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (assign(point, obj)) {
        /* do something with point */
    } else if (assign(segment, obj)) {
        /* do something with segment */
    }

    /* there was no intersection */
}
```

Another way to access the object is to use *object_cast*, which allows to skip a default construction and assignment :

```
{
    typedef Cartesian<double>    K;
    typedef K::Point_2          Point_2;
    typedef K::Segment_2         Segment_2;

    Segment_2 segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (const Point_2 * point = object_cast<Point_2>(&obj)) {
        /* do something with *point */
    }
```

```

    } else if (const Segment_2 * segment = object_cast<Segment_2>(&obj)) {
        /* do something with *segment*/
    }

    /* there was no intersection */
}

```

The intersection routine itself looks roughly as follows:

```

template < class Kernel >
Object intersection(Segment_2<Kernel> s1, Segment_2<Kernel> s2)
{

    if (/* intersection is a point */ ) {

        Point_2<Kernel> p = ... ;
        return make_object(p);

    } else if (/* intersection is a segment */ ) {

        Segment_2<Kernel> s = ... ;
        return make_object(s);
    }

    /* empty intersection */
    return Object();
}

```

CGAL::Null_vector

```
#include <CGAL/Origin.h>
```

Definition

CGAL defines a symbolic constant *NULL_VECTOR* to construct zero length vectors. *Null_vector* is the type of this constant.

See Also

CGAL::Vector_2<Kernel> page [85](#)
CGAL::Vector_3<Kernel> page [116](#)

CGAL::NULL_VECTOR

```
const Null_vector      NULL_VECTOR;
```

Definition

A symbolic constant used to construct zero length vectors.

CGAL::ORIGIN

`const Origin` *ORIGIN*;

Definition

A symbolic constant which denotes the point at the origin. This constant is used in the conversion between points and vectors.

Example

```
Point_2< Cartesian<Exact_NT> >  p(1.0, 1.0), q;
Vector2< Cartesian<Exact_NT> >  v;
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

2.12 Global Functions

CGAL::angle

Angle *angle(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

Angle *angle(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

CGAL::are_ordered_along_line

```
bool are_ordered_along_line( Point_2<Kernel> p,
                             Point_2<Kernel> q,
                             Point_2<Kernel> r)
```

returns *true*, iff the three points are collinear and q lies between p and r . Note that *true* is returned, if $q=p$ or $q=r$.

```

bool      are_ordered_along_line( Point_3<Kernel> p,
                                   Point_3<Kernel> q,
                                   Point_3<Kernel> r)

```

returns *true*, iff the three points are collinear and q lies between p and r . Note that *true* is returned, if $q=p$ or $q=r$.

See Also

<i>CGAL::are_strictly_ordered_along_line</i>	page 137
<i>CGAL::collinear_are_ordered_along_line</i>	page 143
<i>CGAL::collinear_are_strictly_ordered_along_line</i>	page 144

CGAL::are_strictly_ordered_along_line

bool *are_strictly_ordered_along_line*(*Point_2<Kernel>* *p*,
Point_2<Kernel> *q*,
Point_2<Kernel> *r*)

returns *true*, iff the three points are collinear and *q* lies strictly between *p* and *r*. Note that *false* is returned, if $q==p$ or $q==r$.

bool *are_strictly_ordered_along_line*(*Point_3<Kernel>* *p*,
Point_3<Kernel> *q*,
Point_3<Kernel> *r*)

returns *true*, iff the three points are collinear and *q* lies strictly between *p* and *r*. Note that *false* is returned, if $q==p$ or $q==r$.

See Also

CGAL::are_ordered_along_line page [136](#)
CGAL::collinear_are_ordered_along_line page [143](#)
CGAL::collinear_are_strictly_ordered_along_line page [144](#)

CGAL::area*Kernel::FT**area(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns the signed area of the triangle defined by the points p , q and r .

CGAL::bisector

Line_2<Kernel>

bisector(Point_2<Kernel> p, Point_2<Kernel> q)

constructs the bisector line of the two points p and q . The bisector is oriented in such a way that p lies on its positive side.

Precondition: p and q are not equal.

Line_2<Kernel>

bisector(Line_2<Kernel> l1, Line_2<Kernel> l2)

constructs the bisector of the two lines $l1$ and $l2$. In the general case, the bisector has the direction of the vector which is the sum of the normalized directions of the two lines, and which passes through the intersection of $l1$ and $l2$. If $l1$ and $l2$ are parallel, then the bisector is defined as the line which has the same direction as $l1$, and which is at the same distance from $l1$ and $l2$. This function requires that *Kernel::RT* supports the *sqrt()* operation.

Plane_3<Kernel>

bisector(Point_3<Kernel> p, Point_3<Kernel> q)

constructs the bisector plane of the two points p and q . The bisector is oriented in such a way that p lies on its positive side.

Precondition: p and q are not equal.

Plane_3<Kernel>

bisector(Plane_3<Kernel> h1, Plane_3<Kernel> h2)

constructs the bisector of the two planes $h1$ and $h2$. In the general case, the bisector has a normal vector which has the same direction as the sum of the normalized normal vectors of the two planes, and passes through the intersection of $h1$ and $h2$. If $h1$ and $h2$ are parallel, then the bisector is defined as the plane which has the same oriented normal vector as $h1$, and which is at the same distance from $h1$ and $h2$. This function requires that *Kernel::RT* supports the *sqrt()* operation.

CGAL::centroid

Point_2<Kernel> *centroid(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*
 compute the centroid of the points p , q , and r .

Point_2<Kernel> *centroid(Point_2<Kernel> p,*
 Point_2<Kernel> q,
 Point_2<Kernel> r,
 Point_2<Kernel> s)
 compute the centroid of the points p , q , r , and s .

Point_2<Kernel> *centroid(Triangle_2<Kernel> t)*
 compute the centroid of the triangle t .

Point_3<Kernel> *centroid(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*
 compute the centroid of the points p , q , and r .

Point_3<Kernel> *centroid(Point_3<Kernel> p,*
 Point_3<Kernel> q,
 Point_3<Kernel> r,
 Point_3<Kernel> s)
 compute the centroid of the points p , q , r , and s .

Point_3<Kernel> *centroid(Triangle_3<Kernel> t)*
 compute the centroid of the triangle t .

Point_3<Kernel> *centroid(Tetrahedron_3<Kernel> t)*
 compute the centroid of the tetrahedron t .

CGAL::circumcenter

<i>Point_2<Kernel></i>	<i>circumcenter(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)</i>	<p>compute the center of the circle passing through the points p, q, and r.</p> <p><i>Precondition:</i> p, q, and r are not collinear.</p>
<i>Point_2<Kernel></i>	<i>circumcenter(Triangle_2<Kernel> t)</i>	<p>compute the center of the circle passing through the vertices of t.</p> <p><i>Precondition:</i> t is not degenerate.</p>
<i>Point_3<Kernel></i>	<i>circumcenter(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)</i>	<p>compute the center of the circle passing through the points p, q, and r.</p> <p><i>Precondition:</i> p, q, and r are not collinear.</p>
<i>Point_3<Kernel></i>	<i>circumcenter(Triangle_3<Kernel> t)</i>	<p>compute the center of the circle passing through the vertices of t.</p> <p><i>Precondition:</i> t is not degenerate.</p>
<i>Point_3<Kernel></i>	<i>circumcenter(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s)</i>	<p>compute the center of the sphere passing through the points p, q, r, and s.</p> <p><i>Precondition:</i> p, q, r, and s are not coplanar.</p>
<i>Point_3<Kernel></i>	<i>circumcenter(Tetrahedron_3<Kernel> t)</i>	<p>compute the center of the sphere passing through the vertices of t.</p> <p><i>Precondition:</i> t is not degenerate.</p>

CGAL::collinear

bool *collinear*(*Point_2*<*Kernel*> *p*, *Point_2*<*Kernel*> *q*, *Point_2*<*Kernel*> *r*)

returns *true*, iff *p*, *q*, and *r* are collinear.

bool *collinear*(*Point_3*<*Kernel*> *p*, *Point_3*<*Kernel*> *q*, *Point_3*<*Kernel*> *r*)

returns *true*, iff *p*, *q*, and *r* are collinear.

See Also

CGAL::left_turn page [177](#)

CGAL::right_turn page [196](#)

CGAL::collinear_are_ordered_along_line

bool *collinear_are_ordered_along_line*(*Point_2<Kernel>* *p*,
Point_2<Kernel> *q*,
Point_2<Kernel> *r*)

returns *true*, iff *q* lies between *p* and *r*.
Precondition: *p*, *q* and *r* are collinear.

bool *collinear_are_ordered_along_line*(*Point_3<Kernel>* *p*,
Point_3<Kernel> *q*,
Point_3<Kernel> *r*)

returns *true*, iff *q* lies between *p* and *r*.
Precondition: *p*, *q* and *r* are collinear.

See Also

CGAL::are_ordered_along_line page [136](#)
CGAL::are_strictly_ordered_along_line page [137](#)
CGAL::collinear_are_strictly_ordered_along_line page [144](#)

bool *collinear_are_strictly_ordered_along_line*(*Point_2<Kernel>* *p*,
 Point_2<Kernel> *q*,
 Point_2<Kernel> *r*)

returns *true*, iff *q* lies strictly between *p* and *r*.
Precondition: *p*, *q* and *r* are collinear.

bool *collinear_are_strictly_ordered_along_line*(*Point_3<Kernel>* *p*,
 Point_3<Kernel> *q*,
 Point_3<Kernel> *r*)

returns *true*, iff *q* lies strictly between *p* and *r*.
Precondition: *p*, *q* and *r* are collinear.

CGAL::compare_slopes

<i>Comparison_result</i>	<i>compare_slopes(Line_2<Kernel> l1, Line_2<Kernel> l2)</i> compares the slopes of the lines <i>l1</i> and <i>l2</i>
<i>Comparison_result</i>	<i>compare_slopes(Segment_2<Kernel> s1, Segment_2<Kernel> s2)</i> compares the slopes of the segments <i>s1</i> and <i>s2</i>

CGAL::compare_x

Comparison_result *compare_x(Point_2<Kernel> p, Point_2<Kernel> q)*
 compares the x -coordinates of p and q .

Comparison_result *compare_x(Point_3<Kernel> p, Point_3<Kernel> q)*
 compares the x -coordinates of p and q .

Figure 2.1: Comparison of the x or y -coordinates of the (implicitly given) points in the boxes.

Comparison_result *compare_x(Point_2<Kernel> p, Line_2<Kernel> l1, Line_2<Kernel> l2)*
 compares the x -coordinates of p and the intersection of lines $l1$ and $l2$ (Figure 2.1 (a)).

Comparison_result *compare_x(Line_2<Kernel> l, Line_2<Kernel> h1, Line_2<Kernel> h2)*
 compares the x -coordinates of the intersection of line l with line $h1$ and with line $h2$ (Figure 2.1 (b)).

Comparison_result *compare_x(Line_2<Kernel> l1,
 Line_2<Kernel> l2,
 Line_2<Kernel> h1,
 Line_2<Kernel> h2)*
 compares the x -coordinates of the intersection of lines $l1$ and $l2$ and the intersection of lines $h1$ and $h2$ (Figure 2.1 (c)).

CGAL::compare_xy

Comparison_result *compare_xy*(*Point_2*<*Kernel*> *p*, *Point_2*<*Kernel*> *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared.

Comparison_result *compare_xy*(*Point_3*<*Kernel*> *p*, *Point_3*<*Kernel*> *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared.

CGAL::compare_x_at_y

Comparison_result

`compare_x_at_y(Point_2<Kernel> p, Line_2<Kernel> h)`

compares the x -coordinates of p and the horizontal projection of p on h (Figure 2.2 (a)).

Precondition: h is not horizontal.

Figure 2.2: Comparison of the x -coordinates of the (implicitly given) points in the boxes, at a y -coordinate. The y -coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result

`compare_x_at_y(Point_2<Kernel> p, Line_2<Kernel> h1, Line_2<Kernel> h2)`

This function compares the x -coordinates of the horizontal projection of p on $h1$ and on $h2$ (Figure 2.2 (b)).

Precondition: $h1$ and $h2$ are not horizontal.

Comparison_result

`compare_x_at_y(Line_2<Kernel> l1, Line_2<Kernel> l2, Line_2<Kernel> h)`

Let p be the intersection of lines $l1$ and $l2$. This function compares the x -coordinates of p and the horizontal projection of p on h (Figure 2.2 (c)).

Precondition: $l1$ and $l2$ intersect and are not horizontal; h is not horizontal.

Comparison_result

`compare_x_at_y(Line_2<Kernel> l1,
Line_2<Kernel> l2,
Line_2<Kernel> h1,
Line_2<Kernel> h2)`

Let p be the intersection of lines $l1$ and $l2$. This function compares the x -coordinates of the horizontal projection of p on $h1$ and on $h2$ (Figure 2.2 (d)).

Precondition: $l1$ and $l2$ intersect and are not horizontal; $h1$ and $h2$ are not horizontal.

CGAL::compare_y

Comparison_result *compare_y*(*Point_2<Kernel>* *p*, *Point_2<Kernel>* *q*)
 compares Cartesian y-coordinates of *p* and *q*.

Comparison_result *compare_y*(*Point_3<Kernel>* *p*, *Point_3<Kernel>* *q*)
 compares Cartesian y-coordinates of *p* and *q*.

Figure 2.3: Comparison of the x or y-coordinates of the (implicitly given) points in the boxes.

Comparison_result *compare_y*(*Point_2<Kernel>* *p*, *Line_2<Kernel>* *l1*, *Line_2<Kernel>* *l2*)
 compares the y-coordinates of *p* and the intersection of lines *l1* and *l2* (Figure 2.3 (a)).

Comparison_result *compare_y*(*Line_2<Kernel>* *l*, *Line_2<Kernel>* *h1*, *Line_2<Kernel>* *h2*)
 compares the y-coordinates of the intersection of line *l* with line *h1* and with line *h2* (Figure 2.3 (b)).

Comparison_result *compare_y*(*Line_2<Kernel>* *l1*,
 Line_2<Kernel> *l2*,
 Line_2<Kernel> *h1*,
 Line_2<Kernel> *h2*)
 compares the y-coordinates of the intersection of lines *l1* and *l2* and the intersection of lines *h1* and *h2* (Figure 2.3 (c)).

CGAL::compare_y_at_x

Comparison_result

`compare_y_at_x(Point_2<Kernel> p, Line_2<Kernel> h)`

compares the y-coordinates of p and the vertical projection of p on h (Figure 2.4 (d)).

Precondition: h is not vertical.

Figure 2.4: Comparison of the y-coordinates of the (implicitly given) points in the boxes, at an x -coordinate. The x -coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result

`compare_y_at_x(Point_2<Kernel> p, Line_2<Kernel> h1, Line_2<Kernel> h2)`

compares the y-coordinates of the vertical projection of p on $h1$ and on $h2$ (Figure 2.4 (e)).

Precondition: $h1$ and $h2$ are not vertical.

Comparison_result

`compare_y_at_x(Line_2<Kernel> l1, Line_2<Kernel> l2, Line_2<Kernel> h)`

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of p and the vertical projection of p on h (Figure 2.4 (f)).

Precondition: $l1, l2$ intersect and h is not vertical.

Comparison_result

`compare_y_at_x(Line_2<Kernel> l1,
Line_2<Kernel> l2,
Line_2<Kernel> h1,
Line_2<Kernel> h2)`

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of the vertical projection of p on $h1$ and on $h2$ (Figure 2.4 (g)).

Precondition: $l1$ and $l2$ intersect; $h1$ and $h2$ are not vertical.

Comparison_result *compare_y_at_x*(*Point_2*<*Kernel*> *p*, *Segment_2*<*Kernel*> *s*)

compares the y-coordinates of *p* and the vertical projection of *p* on *s*. If *s* is vertical, then return *EQUAL* when *p* lies on *s*, *SMALLER* when *p* lies under *s*, and *LARGER* otherwise.

Precondition: *p* is within the x range of *s*.

Comparison_result *compare_y_at_x*(*Point_2*<*Kernel*> *p*,
 Segment_2<*Kernel*> *s1*,
 Segment_2<*Kernel*> *s2*)

compares the y-coordinates of the vertical projection of *p* on *s1* and on *s2*. If *s1* or *s2* is vertical, then return *EQUAL* if they intersect, otherwise return *SMALLER* if *s1* lies below *s2*, and return *LARGER* otherwise.

Precondition: *p* is within the x range of *s1* and *s2*.

CGAL::compare_yx

Comparison_result *compare_yx*(*Point_2<Kernel> p*, *Point_2<Kernel> q*)

Compares the Cartesian coordinates of points p and q lexicographically in yx order: first y -coordinates are compared, if they are equal, x -coordinates are compared.

CGAL::coplanar

bool *coplanar*(*Point_3*<*Kernel*> *p*,
 Point_3<*Kernel*> *q*,
 Point_3<*Kernel*> *r*,
 Point_3<*Kernel*> *s*)

returns *true*, if *p*, *q*, *r*, and *s* are coplanar.

See Also

CGAL::coplanar_orientation page [162](#)
CGAL::coplanar_side_of_bounded_circle page [163](#)

Orientation

```
coplanar_orientation( Point_3<Kernel> p,
                      Point_3<Kernel> q,
                      Point_3<Kernel> r,
                      Point_3<Kernel> s)
```

Let P be the plane defined by the points p , q , and r . Note that the order defines the orientation of P . The function computes the orientation of points p , q , and s in P : If p , q , s are collinear, *COLLINEAR* is returned. If P and the plane defined by p , q , and s have the same orientation, *POSITIVE* is returned; otherwise *NEGATIVE* is returned. *Precondition*: p , q , r , and s are coplanar and p , q , and r are not collinear.

Orientation

```
coplanar_orientation( Point_3<Kernel> p,
                      Point_3<Kernel> q,
                      Point_3<Kernel> r)
```

If p, q, r are collinear, then *COLLINEAR* is returned. If not, then p, q, r define a plane P . The return value in this case is either *POSITIVE* or *NEGATIVE*, but we don't specify it explicitly. However, we guarantee that all calls to this predicate over 3 points in P will return a coherent orientation if considered a 2D orientation in P .

<i>CGAL::orientation</i>	page 494

CGAL::coplanar_side_of_bounded_circle

Bounded_side

```
coplanar_side_of_bounded_circle( Point_3<Kernel> p,
                                  Point_3<Kernel> q,
                                  Point_3<Kernel> r,
                                  Point_3<Kernel> s)
```

returns the bounded side of the circle defined by p , q , and r on which s lies.

Precondition: p, q, r , and s are coplanar and p, q , and r are not collinear.

See Also

CGAL::coplanar_orientation.....page 162

CGAL::side_of_bounded_circle.....page 197

CGAL::cross_product

Vector_3<Kernel> *cross_product*(*Vector_3<Kernel>* *u*, *Vector_3<Kernel>* *v*)
returns the cross product of *u* and *v*.

CGAL::do_intersect

```
#include <CGAL/intersections.h>
```

```
bool do_intersect( Type1<Kernel> obj1, Type2<Kernel> obj2)
```

checks whether *obj1* and *obj2* intersect. Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*. Note that for objects like triangles and polygons that enclose a bounded region, this region is part of the object.

The types *Type1* and *Type2* can be any of the following:

- *Point_2<Kernel>*
- *Line_2<Kernel>*
- *Ray_2<Kernel>*
- *Segment_2<Kernel>*
- *Triangle_2<Kernel>*
- *Iso_rectangle_2<Kernel>*

Also, in three-dimensional space *Type1* can be *Plane_3<Kernel>* or *Triangle_3<Kernel>* and *Type2* any of

- *Plane_3<Kernel>*
- *Line_3<Kernel>*
- *Ray_3<Kernel>*
- *Segment_3<Kernel>*
- *Triangle_3<Kernel>*

Finally, *Type1* can be of type *Triangle_3<Kernel>* and *Type2* of type *Tetrahedron_3<Kernel>*.

CGAL::do_overlap

```
#include <CGAL/Bbox_2.h>
```

```
bool do_overlap( Bbox_2 bb1, Bbox_2 bb2)
```

returns *true* iff *bb1* and *bb2* overlap, i.e., iff their intersection is non-empty.

```
#include <CGAL/Bbox_3.h>
```

```
bool do_overlap( Bbox_3 bb1, Bbox_3 bb2)
```

returns *true* iff *bb1* and *bb2* overlap, i.e., iff their intersection is non-empty.

CGAL::enum_cast

```
#include <CGAL/functions_on_enums.h>
```

```
template < typename T, typename U >
```

```
T          enum_cast( U u)
```

converts between the various enums provided by the CGAL kernel. The conversion preserves the order of the values.

CGAL::intersection

```
#include <CGAL/intersections.h>
```

```
Object intersection( Type1<Kernel> obj1, Type2<Kernel> obj2)
```

Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*. Note that for objects like triangles and polygons that enclose a bounded region, this region is considered part of the object. If a segment lies completely inside a triangle, then those two objects intersect and the intersection region is the complete segment.

The possible value for types *Type1* and *Type2* and the possible return values wrapped in *Object* are the following:

type A	type B	return type
<i>Line_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Line_2</i>
<i>Segment_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Segment_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Ray_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Ray_2</i>
<i>Ray_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Ray_2</i>	<i>Ray_2</i>	<i>Point_2</i> <i>Segment_2</i> <i>Ray_2</i>
<i>Triangle_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Triangle_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Triangle_2</i>	<i>Ray_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Triangle_2</i>	<i>Triangle_2</i>	<i>Point_2</i> <i>Segment_2</i> <i>Triangle_2</i> <i>std::vector<Point_2></i>
<i>Iso_rectangle_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Iso_rectangle_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Iso_rectangle_2</i>	<i>Ray_2</i>	<i>Point_2</i> <i>Segment_2</i>

continued

<i>Iso_rectangle_2</i>	<i>Iso_rectangle_2</i>	<i>Iso_rectangle_2</i>
<i>Plane_3</i>	<i>Line_3</i>	<i>Point_3</i> <i>Line_3</i>
<i>Plane_3</i>	<i>Ray_3</i>	<i>Point_3</i> <i>Ray_3</i>
<i>Plane_3</i>	<i>Segment_3</i>	<i>Point_3</i> <i>Segment_3</i>
<i>Plane_3</i>	<i>Plane_3</i>	<i>Line_3</i> <i>Plane_3</i>

There is also an intersection function between 3 planes.

Object *intersection(Plane_3<Kernel> pl1, Plane_3<Kernel> pl2, Plane_3<Kernel> pl3)*

returns the intersection of 3 planes, which can be either a point, a line, a plane, or empty.

Example

The following example demonstrates the most common use of *intersection* routines.

```
#include <CGAL/intersections.h>

void foo(CGAL::Segment_2<Kernel> seg, CGAL::Line_2<Kernel> line)
{
    CGAL::Object result;
    CGAL::Point_2<Kernel> ipoint;
    CGAL::Segment_2<Kernel> iseg;

    result = CGAL::intersection(seg, line);
    if (CGAL::assign(ipoint, result)) {

        // handle the point intersection case.

    } else
        if (CGAL::assign(iseg, result)) {

            // handle the segment intersection case.

        } else {

            // handle the no intersection case.

        }
}
```

CGAL::max_vertex

Point_2<Kernel> *max_vertex(Iso_box_2<Kernel> ir)*

computes the vertex with the lexicographically largest coordinates of the iso rectangle *ir*.

Point_3<Kernel> *max_vertex(Iso_cuboid_3<Kernel> ic)*

computes the vertex with the lexicographically largest coordinates of the iso cuboid *ic*.

CGAL::midpoint

Point_2<Kernel> *midpoint(Point_2<Kernel> p, Point_2<Kernel> q)*
computes the midpoint of the segment pq .

Point_3<Kernel> *midpoint(Point_3<Kernel> p, Point_3<Kernel> q)*
computes the midpoint of the segment pq .

CGAL::min_vertex

Point_2<Kernel> *min_vertex(Iso_box_2<Kernel> ir)*

computes the vertex with the lexicographically smallest coordinates of the iso rectangle *ir*.

Point_3<Kernel> *min_vertex(Iso_cuboid_3<Kernel> ic)*

computes the vertex with the lexicographically smallest coordinates of the iso cuboid *ic*.

CGAL::operator+

Point_2<Kernel> *operator+(Point_2<Kernel> p, Vector_2<Kernel> v)*

returns the point obtained by translating p by vector v .

Point_3<Kernel> *operator+(Point_3<Kernel> p, Vector_3<Kernel> v)*

returns a point obtained by translating p by vector v .

See Also

CGAL::operator- page [188](#)
*CGAL::operator** page [189](#)

CGAL::operator-

Vector_2<Kernel> *operator-(Point_2<Kernel> p, Point_2<Kernel> q)*

returns the difference vector between q and p . You can substitute *ORIGIN* for either p or q , but not for both.

Point_2<Kernel> *operator-(Point_2<Kernel> p, Vector_2<Kernel> v)*

returns the point obtained by translating p by the vector $-v$.

Vector_3<Kernel> *operator-(Point_3<Kernel> p, Point_3<Kernel> q)*

returns the difference vector between q and p . You can substitute *ORIGIN* for either p or q , but not both.

Point_3<Kernel> *operator-(Point_3<Kernel> p, Vector_3<Kernel> v)*

returns a point obtained by translating p by the vector $-v$.

See Also

CGAL::operator+ page [187](#)
*CGAL::operator** page [189](#)

CGAL::operator*

Vector_2<Kernel> *operator*(Kernel::RT s, Vector_2<Kernel> w)*

Multiplication with a scalar from the left.

Vector_3<Kernel> *operator*(Kernel::RT s, Vector_3<Kernel> w)*

Multiplication with a scalar from the left.

CGAL::opposite

```
#include <CGAL/functions_on_enums.h>
```

```
Oriented_side                    opposite( Oriented_side o)
```

returns the opposite side (for example *ON_POSITIVE_SIDE* if *o*==*ON_NEGATIVE_SIDE*), or *ON_ORIENTED_BOUNDARY* if *o*==*ON_ORIENTED_BOUNDARY*.

```
Bounded_side                    opposite( Bounded_side o)
```

returns the opposite side (for example *BOUNDED_SIDE* if *o*==*UNBOUNDED_SIDE*), or returns *ON_BOUNDARY* if *o*==*ON_BOUNDARY*.

CGAL::orthogonal_vector

Vector_3<Kernel> *orthogonal_vector(Plane_3<Kernel> p)*

computes an orthogonal vector of the plane p , which is directed to the positive side of this plane.

Vector_3<Kernel> *orthogonal_vector(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

computes an orthogonal vector of the plane defined by p , q and r , which is directed to the positive side of this plane.

CGAL::orientation

Orientation *orientation*(*Point_2*<*Kernel*> *p*, *Point_2*<*Kernel*> *q*, *Point_2*<*Kernel*> *r*)

returns *LEFT_TURN*, if *r* lies to the left of the oriented line *l* defined by *p* and *q*, returns *RIGHT_TURN* if *r* lies to the right of *l*, and returns *COLLINEAR* if *r* lies on *l*.

Orientation *orientation*(*Point_3*<*Kernel*> *p*,
 Point_3<*Kernel*> *q*,
 Point_3<*Kernel*> *r*,
 Point_3<*Kernel*> *s*)

returns *POSITIVE*, if *s* lies on the positive side of the oriented plane *h* defined by *p*, *q*, and *r*, returns *NEGATIVE* if *s* lies on the negative side of *h*, and returns *COPLANAR* if *s* lies on *h*.

CGAL::collinear page [142](#) *CGAL::left_turn* page [177](#) *CGAL::right_turn* page [196](#)

CGAL::parallel

<i>bool</i>	<i>parallel(Line_2<Kernel> l1, Line_2<Kernel> l2)</i>	returns <i>true</i> , if <i>l1</i> and <i>l2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel(Ray_2<Kernel> r1, Ray_2<Kernel> r2)</i>	returns <i>true</i> , if <i>r1</i> and <i>r2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel(Segment_2<Kernel> s1, Segment_2<Kernel> s2)</i>	returns <i>true</i> , if <i>s1</i> and <i>s2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel(Line_3<Kernel> l1, Line_3<Kernel> l2)</i>	returns <i>true</i> , if <i>l1</i> and <i>l2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel(Plane_3<Kernel> h1, Plane_3<Kernel> h2)</i>	returns <i>true</i> , if <i>h1</i> and <i>h2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel(Ray_3<Kernel> r1, Ray_3<Kernel> r2)</i>	returns <i>true</i> , if <i>r1</i> and <i>r2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel(Segment_3<Kernel> s1, Segment_3<Kernel> s2)</i>	returns <i>true</i> , if <i>s1</i> and <i>s2</i> are parallel or if one of those (or both) is degenerate.

CGAL::quotient_cartesian_to_homogeneous

```
#include <CGAL/cartesian_homogeneous_conversion.h>
```

```
Point_2< Homogeneous<RT> >
```

```
quotient_cartesian_to_homogeneous( Point_2< Cartesian< Quotient<RT> > > cp)
```

converts 2d point *cp* with Cartesian representation with number type *Quotient<RT>* into a 2d point with homogeneous representation with number type *RT*.

```
Point_3< Homogeneous<RT> >
```

```
quotient_cartesian_to_homogeneous( Point_3< Cartesian< Quotient<RT> > > cp)
```

converts 3d point *cp* with Cartesian representation with number type *Quotient<RT>* into a 3d point with homogeneous representation with number type *RT*.

CGAL::rational_rotation_approximation

```
#include <CGAL/rational_rotation.h>
```

```
template <RingNumberType>
void rational_rotation_approximation( RingNumberType dirx,
                                     RingNumberType diry,
                                     RingNumberType & sin_num,
                                     RingNumberType & cos_num,
                                     RingNumberType & denom,
                                     RingNumberType eps_num,
                                     RingNumberType eps_den)
```

computes integers *sin_num*, *cos_num* and *denom*, such that *sin_num/denom* approximates the sine of direction (*dirx,diry*). The difference between the sine and the approximating rational is bounded by *eps_num/eps_den*.

Precondition: *eps_num* \neq 0.

Implementation

The approximation is based on Farey sequences as described in the rational rotation method presented by Canny and Ressler at the 8th SoCG 1992. We use a slower version which needs no division operation in the approximation.

CGAL::right_turn

bool *right_turn*(*Point_2*<*Kernel*> *p*, *Point_2*<*Kernel*> *q*, *Point_2*<*Kernel*> *r*)
returns *true* iff *p*, *q*, and *r* form a right turn.

See Also

CGAL::collinear page [142](#)
CGAL::left_turn page [177](#)
CGAL::orientation page [494](#)

CGAL::side_of_bounded_circle

Bounded_side

side_of_bounded_circle(*Point_2*<*Kernel*> *p*,
Point_2<*Kernel*> *q*,
Point_2<*Kernel*> *r*,
Point_2<*Kernel*> *t*)

returns the relative position of point *t* to the circle defined by *p*, *q* and *r*. The order of the points *p*, *q* and *r* does not matter.

Precondition: *p*, *q* and *r* are not collinear.

Bounded_side

side_of_bounded_circle(*Point_2*<*Kernel*> *p*,
Point_2<*Kernel*> *q*,
Point_2<*Kernel*> *t*)

returns the position of the point *t* relative to the circle that has *pq* as its diameter.

See Also

CGAL::coplanar_side_of_bounded_circle page [163](#)
CGAL::side_of_oriented_circle page [199](#)

CGAL::side_of_bounded_sphere

[illegible]

returns the relative position of point t to the sphere defined by p, q, r , and s . The order of the points p, q, r , and s does not matter.

Precondition: p, q, r and s are not coplanar.

$$\text{Bounded_side} \quad \text{side_of_bounded_sphere}(\text{Point_3}\langle\text{Kernel}\rangle p,$$
$$\text{Point_3}\langle\text{Kernel}\rangle q,$$
$$\text{Point_3}\langle\text{Kernel}\rangle r,$$
$$\text{Point_3}\langle\text{Kernel}\rangle t)$$

returns the position of the point t relative to the sphere passing through p , q , and r and whose center is in the plane defined by these three points.

[illegible]

returns the position of the point t relative to the sphere that has pq as its diameter.

See Also

CGAL::side_of_oriented_sphere page 497

returns the relative position of point *test* to the oriented sphere defined by *p*, *q*, *r* and *s*. The order of the points *p*, *q*, *r*, and *s* is important, since it determines the orientation of the implicitly constructed sphere. If the points *p*, *q*, *r* and *s* are positive oriented, positive side is the bounded interior of the sphere.

Precondition: *p*, *q*, *r* and *s* are not coplanar.

CGAL::side_of_bounded_sphere page 496

CGAL::squared_distance

```
#include <CGAL/squared_distance_2.h>
#include <CGAL/squared_distance_3.h>
```

```
Kernel::FT          squared_distance( Type1<Kernel> obj1, Type2<Kernel> obj2)
```

computes the square of the Euclidean distance between two geometric objects. For arbitrary geometric objects *obj1* and *obj2* the squared distance is defined as the minimal *squared_distance(p1, p2)*, where *p1* is a point of *obj1* and *p2* is a point of *obj2*. Note that for objects that have an inside (a bounded region), this inside is part of the object. So, the squared distance from a point inside is zero, not the squared distance to the closest point on the boundary.

In 2D, the types *Type1* and *Type2* can be any of the following:

- *Point_2*
- *Line_2*
- *Ray_2*
- *Segment_2*
- *Triangle_2*

In 3D, the types *Type1* and *Type2* can be any of the following:

- *Point_3*
- *Line_3*
- *Ray_3*
- *Segment_3*
- *Plane_3*

CGAL::squared_radius

- FT* `squared_radius(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)`
- compute the squared radius of the circle passing through the points p , q , and r .
Precondition: p , q , and r are not collinear.
- FT* `squared_radius(Point_2<Kernel> p, Point_2<Kernel> q)`
- compute the squared radius of the smallest circle passing through p , and q , i.e. one fourth of the squared distance between p and q .
- FT* `squared_radius(Point_3<Kernel> p,
Point_3<Kernel> q,
Point_3<Kernel> r,
Point_3<Kernel> s)`
- compute the squared radius of the sphere passing through the points p , q , r and s .
Precondition: p , q , r and s are not coplanar.
- FT* `squared_radius(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)`
- compute the squared radius of the sphere passing through the points p , q , and r and whose center is in the same plane as those three points.
- FT* `squared_radius(Point_3<Kernel> p, Point_3<Kernel> q)`
- compute the squared radius of the smallest circle passing through p , and q , i.e. one fourth of the squared distance between p and q .

2.13 Kernel Function Object Concepts

Kernel::Angle_2

A model for this must provide:

Angle *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*
returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the
angle formed by the three points *p*, *q*, *r* (*q* being the vertex
of the angle).

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::anglepage [135](#)

Kernel::Angle_3

A model for this must provide:

Angle `fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)`
 returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::anglepage [135](#)

Kernel::AreOrderedAlongLine_2

A model for this must provide:

bool *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*
 returns *true*, iff the three points are collinear and *q* lies between *p* and *r*. Note that *true* is returned, if $q=p$ or $q=r$.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::are_ordered_along_line [page 136](#)

Kernel::AreOrderedAlongLine_3

A model for this must provide:

bool *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
 returns *true*, iff the three points are collinear and *q* lies between *p* and *r*. Note that *true* is returned, if $q=p$ or $q=r$.

Refines

AdaptableFunctor (with three arguments)

Kernel::AreParallel_2

A model for this must provide:

bool *fo.operator()*(*Kernel::Line_2* *l1*, *Kernel::Line_2* *l2*)
returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()*(*Kernel::Ray_2* *r1*, *Kernel::Ray_2* *r2*)
returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()*(*Kernel::Segment_2* *s1*, *Kernel::Segment_2* *s2*)
returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::parallel.....page [193](#)

Kernel::AreParallel_3

A model for this must provide:

bool *fo.operator()(Kernel::Line_3 l1, Kernel::Line_3 l2)*
returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Plane_3 h1, Kernel::Plane_3 h2)*
returns *true*, if *h1* and *h2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Ray_3 r1, Kernel::Ray_3 r2)*
returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Segment_3 s1, Kernel::Segment_3 s2)*
returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

CGAL::compare_slopes page 148

Kernel::CompareXAtY_2

A model for this must provide:

Comparison_result *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Line_2* *h*)

compares the x -coordinates of p and the horizontal projection of p on h (Figure 2.5 (a)).

Figure 2.5: Comparison of the x -coordinates of the (implicitly given) points in the boxes, at a y -coordinate. The y -coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Line_2* *h1*, *Kernel::Line_2* *h2*)

compares the x -coordinates of the horizontal projection of p on $h1$ and on $h2$ (Figure 2.5 (b)).

Comparison_result *fo.operator()*(*Kernel::Line_2* *l1*, *Kernel::Line_2* *l2*, *Kernel::Line_2* *h*)

Let p be the intersection of lines $l1$ and $l2$. This function compares the x -coordinates of p and the horizontal projection of p on h (Figure 2.5 (c)).

Comparison_result *fo.operator()*(*Kernel::Line_2* *l1*,
Kernel::Line_2 *l2*,
Kernel::Line_2 *h1*,
Kernel::Line_2 *h2*)

Let p be the intersection of lines $l1$ and $l2$. This function compares the x -coordinates of the horizontal projection of p on $h1$ and on $h2$ (Figure 2.5 (d)).

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::compare_x_at_y page [153](#)

Kernel::CompareXYZ_3

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared. If they are equal, *z*-coordinates are compared.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::compare_xyz page [152](#)

Kernel::CompareXY_2

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*

Compares the Cartesian coordinates of points p and q lexicographically in xy order: first x -coordinates are compared, if they are equal, y -coordinates are compared.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::compare_xy page [151](#)

Kernel::CompareXY_3

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

Compares the Cartesian coordinates of points p and q lexicographically in xy order: first x -coordinates are compared, if they are equal, y -coordinates are compared.

Refines

CGAL::compare_xy page [151](#)

Kernel::CompareX_2

A model for this must provide:

Comparison_result *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Point_2* *q*)

compares the Cartesian *x*-coordinates of points *p* and *q*

Figure 2.6: Comparison of the *x* or *y*-coordinates of the (implicitly given) points in the boxes.

Comparison_result *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Line_2* *l1*, *Kernel::Line_2* *l2*)

compares the *x*-coordinates of *p* and the intersection of lines *l1* and *l2* (Figure 2.6 (a)).

Comparison_result *fo.operator()*(*Kernel::Line_2* *l*, *Kernel::Line_2* *h1*, *Kernel::Line_2* *h2*)

compares the *x*-coordinates of the intersection of line *l* with line *h1* and with line *h2* (Figure 2.6 (b)).

Comparison_result *fo.operator()*(*Kernel::Line_2* *l1*,
Kernel::Line_2 *l2*,
Kernel::Line_2 *h1*,
Kernel::Line_2 *h2*)

compares the *x*-coordinates of the intersection of lines *l1* and *l2* and the intersection of lines *h1* and *h2* (Figure 2.6 (c)).

Kernel::CompareYAtX_2

A model for this must provide:

Comparison_result $fo.operator()(\text{Kernel::Point_2 } p, \text{Kernel::Line_2 } h)$

compares the y-coordinates of p and the vertical projection of p on h (Figure 2.7 (d)).
Precondition: h is not vertical.

Figure 2.7: Comparison of the y-coordinates of the (implicitly given) points in the boxes, at an x -coordinate. The x -coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result $fo.operator()(\text{Kernel::Point_2 } p, \text{Kernel::Line_2 } h1, \text{Kernel::Line_2 } h2)$

This function compares the y-coordinates of the vertical projection of p on $h1$ and on $h2$ (Figure 2.4 (e)).
Precondition: $h1$ and $h2$ are not vertical.

Comparison_result $fo.operator()(\text{Kernel::Line_2 } l1, \text{Kernel::Line_2 } l2, \text{Kernel::Line_2 } h)$

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of p and the vertical projection of p on h (Figure 2.4 (f)).
Precondition: $l1, l2$ intersect and h is not vertical.

Comparison_result $fo.operator()(\text{Kernel::Line_2 } l1, \text{Kernel::Line_2 } l2, \text{Kernel::Line_2 } h1, \text{Kernel::Line_2 } h2)$

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of the vertical projection of p on $h1$ and on $h2$ (Figure 2.4 (g)).
Precondition: $l1$ and $l2$ intersect; $h1$ and $h2$ are not vertical.

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Segment_2 s)*

compares the y-coordinates of *p* and the vertical projection of *p* on *s*. If *s* is vertical, then return *EQUAL* when *p* lies on *s*, *SMALLER* when *p* lies under *s*, and *LARGER* otherwise.

Precondition: *p* is within the x range of *s*.

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Segment_2 s1, Kernel::Segment_2 s2)*

This function compares the y-coordinates of the vertical projection of *p* on *s1* and on *s2*. If *s1* or *s2* is vertical, then return *EQUAL* if they intersect, otherwise return *SMALLER* if *s1* lies below *s2*, and return *LARGER* otherwise.

Precondition: *p* is within the x range of *s1* and *s2*.

Kernel::CompareY_2

A model for this must provide:

Comparison_result *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Point_2* *q*)

Compares the Cartesian y-coordinates of points *p* and *q*

Figure 2.8: Comparison of the x or y-coordinates of the (implicitly given) points in the boxes.

Comparison_result *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Line_2* *l1*, *Kernel::Line_2* *l2*)

compares the y-coordinates of *p* and the intersection of lines *l1* and *l2* (Figure 2.8 (a)).

Comparison_result *fo.operator()*(*Kernel::Line_2* *l*, *Kernel::Line_2* *h1*, *Kernel::Line_2* *h2*)

compares the y-coordinates of the intersection of line *l* with line *h1* and with line *h2* (Figure 2.8 (b)).

Comparison_result *fo.operator()*(*Kernel::Line_2* *l1*,
Kernel::Line_2 *l2*,
Kernel::Line_2 *h1*,
Kernel::Line_2 *h2*)

compares the y-coordinates of the intersection of lines *l1* and *l2* and the intersection of lines *h1* and *h2* (Figure 2.8 (c)).

returns the bounding box of *s*.

Refines

AdaptableFunctor (with one argument)

Kernel::ConstructBisector_2

A model for this must provide:

Kernel::Line_2 *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*

constructs the bisector of p and q . The bisector is oriented in such a way that p lies on its positive side.

Precondition: p and q are not equal.

Kernel::Line_2 *fo.operator()(Kernel::Line_2 l1, Kernel::Line_2 l2)*

constructs the bisector of the two lines $l1$ and $l2$. In the general case, the bisector has the direction of the vector which is the sum of the normalized directions of the two lines, and which passes through the intersection of $l1$ and $l2$. If $l1$ and $l2$ are parallel, then the bisector is defined as the line which has the same direction as $l1$, and which is at the same distance from $l1$ and $l2$. This function requires that *Kernel::RT* supports the *sqrt()* operation.

Refines

AdaptableFunctor (with two arguments)

$$\text{Kernel::Iso_cuboid_3} \quad fo.operator()(\text{Kernel::Point_3 } p, \text{Kernel::Point_3 } q)$$

introduces an iso-oriented cuboid with diagonal opposite vertices p and q such that p is the lexicographically smallest point in the cuboid.

Kernel::Iso_cuboid_3 *fo.operator() (Kernel::Point_3 left,*
 Kernel::Point_3 right,
 Kernel::Point_3 bottom,
 Kernel::Point_3 top,
 Kernel::Point_3 far,
 Kernel::Point_3 close)

introduces an iso-oriented cuboid *fo* whose minimal *x* coordinate is the one of *left*, the maximal *x* coordinate is the one of *right*, the minimal *y* coordinate is the one of *bottom*, the maximal *y* coordinate is the one of *top*, the minimal *z* coordinate is the one of *far*, the maximal *z* coordinate is the one of *close*.

Kernel::ConstructIsoRectangle_2

A model for this must provide:

$$\text{Kernel::Iso_rectangle_2} \quad fo.operator()(\text{Kernel::Point_2 } p, \text{Kernel::Point_2 } q)$$

introduces an iso-oriented rectangle with diagonal opposite vertices p and q such that p is the lexicographically smallest point in the rectangle.

```
Kernel::Iso_rectangle_2   fo.operator() ( Kernel::Point_2 left,
                             Kernel::Point_2 right,
                             Kernel::Point_2 bottom,
                             Kernel::Point_2 top)
```

introduces an iso-oriented rectangle *fo* whose minimal *x* coordinate is the one of *left*, the maximal *x* coordinate is the one of *right*, the minimal *y* coordinate is the one of *bottom*, the maximal *y* coordinate is the one of *top*.

Refines

AdaptableFunctor (with two arguments)

CGAL::Iso_rectangle_2<Kernel> page 69

Kernel::ConstructLiftedPoint_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Plane_3 h, Kernel::Point_2 p)*

returns a point q on plane h , such that the projection of this point onto the xy -plane is p .

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> [page 99](#)

Kernel::ConstructLine_2

A model for this must provide:

$$\text{Kernel::Line_2} \quad fo.operator()(\text{Kernel::Point_2 } p, \text{Kernel::Point_2 } q)$$

introduces a line passing through the points p and q . Line is directed from p to q .

```
Kernel::Line_2 fo.operator() ( Kernel::Point_2 p, Kernel::Direction_2 d)
```

introduces a line passing through point p with direction d .

```
Kernel::Line_2      fo.operator()( Kernel::Point_2 p, Kernel::Vector_2 v)
```

introduces a line passing through point p and oriented by ν .

$$Kernel::Line_2 \quad fo.operator() (Kernel::Segment_2 s)$$

introduces a line supporting the segment s , oriented from source to target.

$$Kernel::Line_2 \quad fo.operator() (Kernel::Ray_2 \ r)$$

introduces a line supporting the ray r , with same orientation.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_2<Kernel> page 72

Kernel::ConstructLine_3

A model for this must provide:

Kernel::Line_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*
introduces a line passing through the points *p* and *q*. Line is directed from *p* to *q*.

Kernel::Line_3 *fo.operator()(Kernel::Point_3 p, Kernel::Vector_3 v)*
introduces a line passing through point *p* and oriented by *v*.

Kernel::Line_3 *fo.operator()(Kernel::Point_3 p, Kernel::Direction_3 d)*
introduces a line passing through point *p* with direction *d*.

Kernel::Line_3 *fo.operator()(Kernel::Segment_3 s)*
returns the line supporting the segment *s*, oriented from source to target.

Kernel::Line_3 *fo.operator()(Kernel::Ray_3 r)*
returns the line supporting the ray *r*, with the same orientation.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_3<Kernel> page [97](#)

Kernel::ConstructMaxVertex_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Iso_rectangle_2 r)*
 returns the vertex of *r* with lexicographically largest co-ordinates.

Kernel::Point_2 *fo.operator()(Kernel::Segment_2 s)*
 returns the vertex of *s* with lexicographically largest co-ordinates.

Refines

AdaptableFunctor (with one argument)

Kernel::ConstructOppositeCircle_2

A model for this must provide:

Kernel::Circle_2 *fo.operator()(Kernel::Circle_2 c)*

returns the circle with the same center and squared radius as *c*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Circle_2<Kernel>page [65](#)

$$\text{Kernel}::\text{Direction_2} \quad \text{fo.operator()}(\text{Kernel}::\text{Direction_2 } d)$$

returns the direction opposite to d .

AdaptableFunctor (with one argument)

CGAL::Direction_2<Kernel>page 67

Kernel::ConstructOppositeDirection_3

A model for this must provide:

```
Kernel::Direction_3      fo.operator()( Kernel::Direction_3 d)
                                returns the direction opposite to d.
```

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Direction_3<Kernel>.....page [92](#)

Kernel::ConstructOppositeLine_2

A model for this must provide:

Kernel::Line_2 *fo.operator()(Kernel::Line_2 l)*

returns the line representing the same set of points as *l*,
but with opposite direction.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Line_2<Kernel> [page 72](#)

Kernel::ConstructOppositeLine_3

A model for this must provide:

Kernel::Line_3 *fo.operator()(Kernel::Line_3 l)*

returns the line representing the same set of points as *l*,
but with opposite direction.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Line_3<Kernel> page [97](#)

Kernel::ConstructOppositePlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::Plane_3 p)*

returns the plane representing the same set of points as *p*,
but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Plane_3<Kernel> [page 99](#)

Kernel::ConstructOppositeRay_2

A model for this must provide:

Kernel::Ray_2 *fo.operator()(Kernel::Ray_2 r)*

returns the ray with the same source as *r*, but in opposite direction.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Ray_2<Kernel>page [79](#)

Kernel::ConstructOppositeRay_3

A model for this must provide:

Kernel::Ray_3 *fo.operator()(Kernel::Ray_3 r)*

returns the ray with the same source as *r*, but in opposite direction.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Ray_3<Kernel>page [105](#)

Kernel::ConstructOppositeSegment_2

A model for this must provide:

Kernel::Segment_2 *fo.operator()(Kernel::Segment_2 s)*

returns the segment representing the same set of points as *s*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Segment_2<Kernel>page [81](#)

Kernel::ConstructOppositeSegment_3

A model for this must provide:

Kernel::Segment_3 *fo.operator()(Kernel::Segment_3 s)*

returns the segment representing the same set of points as *s*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Segment_3<Kernel>.....page [107](#)

Kernel::ConstructOppositeSphere_3

A model for this must provide:

Kernel::Sphere_3 *fo.operator()(Kernel::Sphere_3 s)*

returns the sphere with the same center and squared radius as *s*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Sphere_3<Kernel> [page 109](#)

Kernel::ConstructOppositeTriangle_2

A model for this must provide:

Kernel::Triangle_2 *fo.operator()(Kernel::Triangle_2 t)*

returns the triangle with opposite orientation to *t* (this flips the positive and the negative side, but not bounded and unbounded side).

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Triangle_2<Kernel>page [83](#)

Kernel::ConstructOppositeVector_2

A model for this must provide:

```
Kernel::Vector_2      fo.operator()( Kernel::Vector_2 v)
                        returns the vector -v.
```

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Vector_2<Kernel> page [85](#)

Kernel::Vector_3 *fo.operator() (Kernel::Vector_3 v)*

returns the vector -v.

AdaptableFunctor (with one argument)

CGAL::Vector_3<Kernel> page 116

Kernel::ConstructOrthogonalVector_3

A model for this must provide:

Kernel::Vector_3 *fo.operator()(Kernel::Plane_3 p)*

returns a vector that is orthogonal to the plane *p* and directed to the positive side of *p*.

Kernel::Vector_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

returns a vector that is orthogonal to the plane defined by *Kernel::ConstructPlane_3()(p, q, r)* and directed to the positive side of this plane.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Plane_3<Kernel> page [99](#)
Kernel::ConstructCrossProductVector_3 page [280](#)

Kernel::ConstructPerpendicularDirection_2

A model for this must provide:

Kernel::Direction_2 *fo.operator()(Kernel::Direction_2 d, Orientation o)*

introduces a direction orthogonal to *d*. If *o* is *CLOCKWISE*, *d* is rotated clockwise; if *o* is *COUNTERCLOCKWISE*, *d* is rotated counterclockwise.
Precondition: o is not *COLLINEAR*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Direction_2<Kernel>page [67](#)

Kernel::ConstructPerpendicularLine_2

A model for this must provide:

Kernel::Line_2 *fo.operator()(Kernel::Line_2 l, Kernel::Point_2 p)*

returns the line perpendicular to *l* and passing through *p*, where the direction is the direction of *l* rotated counter-clockwise by 90 degrees.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_2<Kernel> [page 72](#)

Kernel::ConstructPerpendicularLine_3

A model for this must provide:

Kernel::Line_3 *fo.operator()(Kernel::Plane_3 pl, Kernel::Point_3 p)*

returns the line that is perpendicular to *pl* and that passes through point *p*. The line is oriented from the negative to the positive side of *pl*

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> [page 99](#)

Kernel::ConstructPerpendicularPlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::Line_3 l, Kernel::Point_3 p)*

returns the plane perpendicular to *l* passing through *p*,
such that the normal direction of the plane coincides with
the direction of the line.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> page [99](#)

Kernel::ConstructPerpendicularVector_2

A model for this must provide:

Kernel::Vector_2 *fo.operator()(Kernel::Vector_2 v, Orientation o)*

returns *v* rotated clockwise by 90 degrees, if *o* is *CLOCKWISE*, and rotated counterclockwise otherwise.
Precondition: o is not *COLLINEAR*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Vector_2<Kernel> page [85](#)

Kernel::ConstructPlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::RT a, Kernel::RT b, Kernel::RT c, Kernel::RT d)*

creates a plane defined by the equation $apx + bpy + cz + d = 0$. Notice that is degenerate if $a = b = c$.

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

creates a plane passing through the points p , q and r . The plane is oriented such that p , q and r are oriented in a positive sense (that is counterclockwise) when seen from the positive side of the plane. Notice that is degenerate if the points are collinear.

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Direction_3 d)*

introduces a plane that passes through point p and that has as an orthogonal direction equal to d .

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Vector_3 v)*

introduces a plane that passes through point p and that is orthogonal to v .

Kernel::Plane_3 *fo.operator()(Kernel::Line_3 l, Kernel::Point_3 p)*

introduces a plane that is defined through the three points $l.point(0)$, $l.point(1)$ and p .

Kernel::Plane_3 *fo.operator()(Kernel::Ray_3 r, Kernel::Point_3 p)*

introduces a plane that is defined through the three points $r.point(0)$, $r.point(1)$ and p .

Kernel::Plane_3 *fo.operator()(Kernel::Segment_3 s, Kernel::Point_3 p)*

introduces a plane that is defined through the three points $s.source()$, $s.target()$ and p .

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> page [99](#)

Kernel::ConstructPointOn_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Line_2 l, int i)*

returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all *i < j*.

Kernel::Point_2 *fo.operator()(Kernel::Ray_2 r, int i)*

returns a point on *r*. *point(0)* is the source, *point(i)*, with *i > 0*, is different from the source.
Precondition: i ≥ 0.

Kernel::Point_2 *fo.operator()(Kernel::Segment_2 s, int i)*

returns source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. The parameter *i* is taken modulo 2, which gives easy access to the other end point.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_2<Kernel> page [72](#)

CGAL::Segment_2<Kernel> page [81](#)

Kernel::ConstructPointOn_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Line_3 l, int i)*

returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all *i < j*.

Kernel::Point_3 *fo.operator()(Kernel::Plane_3 h)*

returns an arbitrary point on *h*.

Kernel::Point_3 *fo.operator()(Kernel::Ray_3 r, int i)*

returns a point on *r*. *point(0)* is the source, *point(i)*, with *i > 0*, is different from the source.
Precondition: i ≥ 0.

Kernel::Point_3 *fo.operator()(Kernel::Segment_3 s, int i)*

returns source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. The parameter *i* is taken modulo 2, which gives easy access to the other end point.

Refines

AdaptableFunctor (with two arguments)

CGAL::Point_3<Kernel> page [102](#)

Kernel::ConstructProjectedPoint_2

A model for this must provide:

```
Kernel::Point_2      fo.operator()( Kernel::Line_2 l, Kernel::Point_2 p)
```

returns the orthogonal projection of p onto l .

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_2<Kernel> page 72

Kernel::Point_3 *fo.operator()*(*Kernel::Line_3* *l*, *Kernel::Point_3* *p*)

returns the orthogonal projection of *p* onto *l*.

Kernel::Point_3 *fo.operator() (Kernel::Plane_3 h, Kernel::Point_3 p)*

returns the orthogonal projection of *p* onto *h*.

AdaptableFunctor (with two arguments)

<i>CGAL::Line_3<Kernel></i>	page 97
<i>CGAL::Plane_3<Kernel></i>	page 99

Kernel::ConstructProjectedXYPoint_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Plane_3 h, Kernel::Point_3 p)*

returns the image point of the projection of p under an affine transformation, which maps h onto the xy -plane, with the z -coordinate removed.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> page [99](#)

Kernel::ConstructRay_2

A model for this must provide:

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*
introduces a ray with source *p* and passing through point *q*.

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Vector_2 v)*
introduces a ray starting at source *p* with the direction given by *v*.

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Direction_2 d)*
introduces a ray starting at source *p* with direction *d*.

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Line_2 l)*
introduces a ray starting at source *p* with the same direction as *l*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Vector_3<Kernel> page [116](#)

Kernel::ConstructSumOfVectors_2

A model for this must provide:

Kernel::Vector_2 *fo.operator()(Kernel::Vector_2 v1, Kernel::Vector_2 v2)*

introduces the vector $v1 + v2$.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Vector_2<Kernel> page [85](#)

Kernel::ConstructSegment_2

A model for this must provide:

Kernel::Segment_2 *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*

introduces a segment with source p and target q . The segment is directed from the source towards the target.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Segment_2<Kernel>page [81](#)

Kernel::ConstructSegment_3

A model for this must provide:

Kernel::Segment_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

introduces a segment with source *p* and target *q*. It is directed from the source towards the target.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Segment_3<Kernel>.....page [107](#)

Kernel::ConstructSphere_3

A model for this must provide:

Kernel::Sphere_3 *fo.operator()*(*Kernel::Point_3* center,
 Kernel::FT squared_radius,
 Orientation orientation = COUNTERCLOCKWISE)

introduces a sphere initialized to the sphere with center *center*, squared radius *squared_radius* and orientation *orientation*.

Precondition: *orientation* \neq COPLANAR, and furthermore, *squared_radius* \geq 0.

Kernel::Sphere_3 *fo.operator()*(*Kernel::Point_3* p,
 Kernel::Point_3 q,
 Kernel::Point_3 r,
 Kernel::Point_3 s)

introduces a sphere initialized to the unique sphere which passes through the points *p*, *q*, *r* and *s*. The orientation of the sphere is the orientation of the point quadruple *p*, *q*, *r*, *s*.

Precondition: *p*, *q*, *r*, and *s* are not collinear.

Kernel::Sphere_3 *fo.operator()*(*Kernel::Point_3* p,
 Kernel::Point_3 q,
 Kernel::Point_3 r,
 Orientation o = COUNTERCLOCKWISE)

introduces a sphere initialized to the smallest sphere which passes through the points *p*, *q*, and *r*. The orientation of the sphere is *o*.

Precondition: *o* is not COPLANAR.

Kernel::Sphere_3 *fo.operator()*(*Kernel::Point_3* p,
 Kernel::Point_3 q,
 Orientation o = COUNTERCLOCKWISE)

introduces a sphere initialized to the smallest sphere which passes through the points *p* and *q*. The orientation of the sphere is *o*.

Precondition: *o* is not COPLANAR.

Kernel::Sphere_3 *fo.operator()*(*Kernel::Point_3* center,
 Orientation orientation = COUNTERCLOCKWISE)

introduces a sphere *s* initialized to the sphere with center *center*, squared radius zero and orientation *orientation*.

Precondition: *orientation* \neq COPLANAR.

Postcondition: *s.is_degenerate()* = true.

Refines

AdaptableFunctor (with four arguments)

See Also

CGAL::Sphere_3<Kernel> [page 109](#)

Kernel::ConstructSupportingPlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::Triangle_3 t)*

returns the supporting plane of *t*, with same orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Triangle_3<Kernel> page [114](#)

Kernel::ConstructTetrahedron_3

A model for this must provide:

```
Kernel::Tetrahedron_3    fo.operator()( Kernel::Point_3 p0,
                                         Kernel::Point_3 p1,
                                         Kernel::Point_3 p2,
                                         Kernel::Point_3 p3)
```

introduces a tetrahedron with vertices p_0 , p_1 , p_2 and p_3 .

Refines

AdaptableFunctor (with four arguments)

See Also

CGAL::Tetrahedron_3<Kernel> page [112](#)

Kernel::ConstructTranslatedPoint_2

A model for this must provide:

```
Kernel::Point_2      fo.operator()( Kernel::Point_2 p, Kernel::Vector_2 v)
```

returns the point obtained by translating p by the vector v .

```
Kernel::Point_2      fo.operator()( Origin o, Kernel::Vector_2 v)
```

returns the point obtained by translating a point at the origin by the vector v .

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Point_2<Kernel> page 75

$$\text{Kernel::Point_3} \quad fo.operator()(\text{Kernel::Point_3 } p, \text{Kernel::Vector_3 } v)$$

$$\text{Kernel::Triangle_3} \quad fo.operator()(\text{Kernel::Point_3 } p, \text{Kernel::Point_3 } q, \text{Kernel::Point_3 } r)$$

introduces a triangle with vertices p , q and r .

AdaptableFunctor (with three arguments)

CGAL::Triangle_3<Kernel> page 114

Kernel::ConstructVector_2

A model for this must provide:

Kernel::Vector_2 *fo.operator()(Kernel::Point_2 a, Kernel::Point_2 b)*
introduces the vector $b - a$.

Kernel::Vector_2 *fo.operator()(Origin o, Kernel::Point_2 b)*
introduces the vector b .

Kernel::Vector_2 *fo.operator()(Kernel::Point_2 a, Origin o)*
introduces the vector $-a$.

Kernel::Vector_2 *fo.operator()(Kernel::Segment_2 s)*
introduces the vector $s.target() - s.source()$.

Kernel::Vector_2 *fo.operator()(Kernel::Ray_2 r)*
introduces a vector having the same direction as r .

Kernel::Vector_2 *fo.operator()(Kernel::Line_2 l)*
introduces a vector having the same direction as l .

Kernel::Vector_2 *fo.operator()(Null_vector NULL_VECTOR)*
introduces a null vector .

Kernel::ConstructVertex_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Segment_2 s, int i)*

returns source or target of *s*: *fo(s,0)* returns the source of *s*, *fo(s,1)* returns the target of *s*. The parameter *i* is taken modulo 2.

Kernel::Point_2 *fo.operator()(Kernel::Iso_rectangle_2 r, int i)*

returns the *i*'th vertex of *r* in counterclockwise order, starting with the lower left vertex. The parameter *i* is taken modulo 4.

Kernel::Point_2 *fo.operator()(Kernel::Triangle_2 t, int i)*

returns the *i*'th vertex of *t*. The parameter *i* is taken modulo 3.

Refines

AdaptableFunctor (with two arguments)

Kernel::ConstructVertex_3

A model for this must provide:

Kernel::Point_3 *fo.operator() (Kernel::Segment_3 s, int i)*

returns source or target of s : $fo(s,0)$ returns the source of s , $fo(s,1)$ returns the target of s . The parameter i is taken modulo 2.

Kernel::Point_3 *fo.operator() (Kernel::Iso_cuboid_3 c, int i)*

returns the i 'th vertex of c , as indicated in the figure below. The parameter i is taken modulo 8.

Kernel::Point_3 *fo.operator() (Kernel::Triangle_3 t, int i)*

returns the i 'th vertex of t . The parameter i is taken modulo 3.

Kernel::Point_3 *fo.operator() (Kernel::Tetrahedron_3 t, int i)*

returns the i 'th vertex of t . The parameter i is taken modulo 4.

Kernel::ConstructCartesianConstIterator_3 page [272](#)

Kernel::CoplanarOrientation_3

A model for this must provide:

Orientation `fo.operator()(Kernel::Point_3 p,
Kernel::Point_3 q,
Kernel::Point_3 r,
Kernel::Point_3 s)`

Let P be the plane defined by the points p , q , and r . Note that the order defines the orientation of P . The function computes the orientation of points p , q , and s in P : Iff p , q , s are collinear, *COLLINEAR* is returned. Iff P and the plane defined by p , q , and s have the same orientation, *POSITIVE* is returned; otherwise *NEGATIVE* is returned. *Precondition*: p , q , r , and s are coplanar and p , q , and r are not collinear.

Orientation `fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)`

If p, q, r are collinear, then *COLLINEAR* is returned. If not, then p, q, r define a plane P . The return value in this case is either *POSITIVE* or *NEGATIVE*, but we don't specify it explicitly. However, we guarantee that all calls to this predicate over 3 points in P will return a coherent orientation if considered a 2D orientation in P .

CGAL::coplanar_orientationpage [162](#)

$$\text{Bounded_side} \quad fo.operator() (Kernel::Point_3 p, \\ Kernel::Point_3 q, \\ Kernel::Point_3 r, \\ Kernel::Point_3 s)$$

Precondition: p , q , r , and s are coplanar and p , q , and r are not collinear.

AdaptableFunctor (with four arguments)

CGAL::coplanar_side_of_bounded_circle page 163

Kernel::Coplanar_3

A model for this must provide:

```
bool                                fo.operator()( Kernel::Point_3 p,
                                                    Kernel::Point_3 q,
                                                    Kernel::Point_3 r,
                                                    Kernel::Point_3 s)

                                returns true, if p, q, r, and s are coplanar.
```

Refines

AdaptableFunctor (with four arguments)

CGAL::coplanarpage [161](#)

Kernel::CounterclockwiseInBetween_2

A model for this must provide:

```
bool                                fo.operator()( Kernel::Direction_2 d,
                                                    Kernel::Direction_2 d1,
                                                    Kernel::Direction_2 d2)
```

returns *true* iff *d* is not equal to *d1*, and while rotating counterclockwise starting at *d1*, *d* is reached strictly before *d2* is reached. Note that true is returned if *d1* == *d2*, unless also *d* == *d1*.

Kernel::IsDegenerate_3

A model for this must provide:

bool *fo.operator()(Kernel::Iso_cuboid_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Line_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Plane_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Ray_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Segment_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Sphere_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Tetrahedron_3 o)*
returns true iff *o* is degenerate.

bool *fo.operator()(Kernel::Triangle_3 o)*
returns true iff *o* is degenerate.

Kernel::IsHorizontal_2

A model for this must provide:

bool *fo.operator()(Kernel::Line_2 o)*
returns true iff *o* is horizontal.

bool *fo.operator()(Kernel::Ray_2 o)*
returns true iff *o* is horizontal.

bool *fo.operator()(Kernel::Segment_2 o)*
returns true iff *o* is horizontal.

Kernel::IsVertical_2

A model for this must provide:

bool *fo.operator()(Kernel::Line_2 o)*
returns true iff *o* is vertical.

bool *fo.operator()(Kernel::Ray_2 o)*
returns true iff *o* is vertical.

bool *fo.operator()(Kernel::Segment_2 o)*
returns true iff *o* is vertical.

Kernel::LeftTurn_2

A model for this must provide:

bool *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Point_2* *q*, *Kernel::Point_2* *r*)
returns *true*, iff the three points *p*, *q* and *r* form a left turn.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::left_turn page [177](#)

Kernel::LessDistanceToPoint_2

A model for this must provide:

bool *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*
 returns true iff the distance of *q* to *p* is smaller than the distance of *r* to *p*.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::has_smaller_distance_to_point page [171](#)

Kernel::LessDistanceToPoint_3

A model for this must provide:

bool *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
 returns true iff the distance of *q* to *p* is smaller than the distance of *r* to *p*.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::has_smaller_distance_to_point page [171](#)

Kernel::LessRotateCCW_2

A model for this must provide:

bool *fo.operator()*(*Kernel::Point_2* *p*, *Kernel::Point_2* *q*, *Kernel::Point_2* *r*)

returns true iff the three points *p*, *q* and *r* form a left turn or if they are collinear and the distance of *q* to *p* is larger than the distance of *r* to *p*, where *p* is the point passed to the object at construction.

Precondition: *p* does not lie in the interior of the segment *rq*, i.e. *p* is an extreme point with respect to $\{p, q, r\}$.

Refines

AdaptableFunctor (with three arguments)

Kernel::LessSignedDistanceToLine_2

A model for this must provide:

bool *fo.operator()*(*Kernel::Line_2* *l*, *Kernel::Point_2* *p*, *Kernel::Point_2* *q*)
returns *true* if the signed distance from *p* and the oriented line *l* is smaller than the signed distance of *q* and *l*.

bool *fo.operator()*(*Kernel::Point_2* *p*,
Kernel::Point_2 *q*,
Kernel::Point_2 *r*,
Kernel::Point_2 *s*)
returns *true* if the signed distance from *r* and the oriented line *l* defined by *p* and *q* is smaller than the signed distance of *s* and *l*.
Precondition: *p*! = *q*.

Refines

AdaptableFunctor (with four arguments)

See Also

CGAL::has_smaller_signed_distance_to_line page [172](#)

Kernel::LessSignedDistanceToPlane_3

A model for this must provide:

bool *fo.operator()*(*Kernel::Plane_3* *p*, *Kernel::Point_3* *q*, *Kernel::Point_3* *r*)

returns true, iff the signed distance from point *q* to plane *p* is smaller than the signed distance from point *r* to *p*.

bool *fo.operator()*(*Kernel::Point_3* *p1*,
Kernel::Point_3 *p2*,
Kernel::Point_3 *p3*,
Kernel::Point_3 *q*,
Kernel::Point_3 *r*)

returns true, iff the signed distance from point *q* to the plane *p* defined by *p1*, *p2*, *p3* is smaller than the signed distance from point *r* to *p*.
Precondition: *p*, *q*, and *r* are not collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::has_smaller_signed_distance_to_plane page [173](#)

Kernel::LessXYZ_3

A model for this must provide:

bool *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

returns true iff the x -coordinate of p is smaller than the x -coordinate of q or if they are the same and the y -coordinate of p is smaller than the y -coordinate of q , or, if both x - and y -coordinate are identical and the z -coordinate of p is smaller than the z -coordinate of q .

Refines

AdaptableFunctor (with two arguments)

See Also

Kernel::Orientation_2

A model for this must provide:

Orientation $fo.operator()(\text{Kernel::Point_2 } p, \text{Kernel::Point_2 } q, \text{Kernel::Point_2 } r)$

returns *LEFT_TURN*, if r lies to the left of the oriented line l defined by p and q , returns *RIGHT_TURN* if r lies to the right of l , and returns *COLLINEAR* if r lies on l .

Orientation $fo.operator()(\text{Kernel::Vector_2 } u, \text{Kernel::Vector_2 } v)$

returns *LEFT_TURN* if u and v form a left turn, returns *RIGHT_TURN* if u and v form a right turn, and returns *COLLINEAR* if u and v are collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::orientationpage [494](#)

Kernel::Orientation_3

A model for this must provide:

Orientation *fo.operator()(Kernel::Point_3 p,*
 Kernel::Point_3 q,
 Kernel::Point_3 r,
 Kernel::Point_3 s)

returns *POSITIVE*, if *s* lies on the positive side of the oriented plane *h* defined by *p*, *q*, and *r*, returns *NEGATIVE* if *s* lies on the negative side of *h*, and returns *COPLANAR* if *s* lies on *h*.

Orientation *fo.operator()(Kernel::Vector_3 u, Kernel::Vector_3 v, Kernel::Vector_3 w)*

returns *POSITIVE* if *u*, *v* and *w* are positively oriented, returns *NEGATIVE* if *u*, *v* and *w* are negatively oriented, and returns *COPLANAR* if *u*, *v* and *w* are coplanar.

Refines

AdaptableFunctor (with four arguments)

See Also

CGAL::orientationpage [494](#)

Kernel::OrientedSide_2

A model for this must provide:

Oriented_side *fo.operator()(Kernel::Circle_2 c, Kernel::Point_2 p)*

returns *ON_ORIENTED_BOUNDARY*, *ON_NEGATIVE_SIDE*, or the constant *ON_POSITIVE_SIDE*, depending on the position of *p* relative to the oriented circle *c*.

Oriented_side *fo.operator()(Kernel::Line_2 l, Kernel::Point_2 p)*

returns *ON_ORIENTED_BOUNDARY*, *ON_NEGATIVE_SIDE*, or the constant *ON_POSITIVE_SIDE*, depending on the position of *p* relative to the oriented line *l*.

Oriented_side *fo.operator()(Kernel::Triangle_2 t, Kernel::Point_2 p)*

returns *ON_ORIENTED_BOUNDARY*, *ON_NEGATIVE_SIDE*, or the constant *ON_POSITIVE_SIDE*, depending on the position of *p* relative to the oriented triangle *t*.

Refines

Kernel::SideOfBoundedSphere_3

A model for this must provide:

```
Bounded_side      fo.operator()( Kernel::Point_3 p,
                                   Kernel::Point_3 q,
                                   Kernel::Point_3 r,
                                   Kernel::Point_3 s,
                                   Kernel::Point_3 t)
```

returns the relative position of point t to the sphere defined by p, q, r , and s . The order of the points p, q, r , and s does not matter.

Precondition: p, q, r and s are not coplanar.

<i>Bounded_side</i>	<i>fo.operator()</i> (<i>Kernel::Point_3</i> <i>p</i> , <i>Kernel::Point_3</i> <i>q</i> , <i>Kernel::Point_3</i> <i>r</i> , <i>Kernel::Point_3</i> <i>t</i>)
---------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------

returns the position of the point t relative to the sphere passing through p , q , and r and whose center is in the plane defined by these three points.

<i>Bounded_side</i>	<i>fo.operator()</i> (<i>Kernel::Point_3</i> <i>p</i> , <i>Kernel::Point_3</i> <i>q</i> , <i>Kernel::Point_3</i> <i>t</i>)
---------------------	------------------------------------------------------------------------------------------------------------------------------

returns the position of the point t relative to the sphere that has pq as its diameter.

Refines

AdaptableFunctor (with five arguments)

Kernel::SideOfOrientedSphere_3

A model for this must provide:

<i>Oriented_side</i>	<i>fo.operator()</i> (<i>Kernel::Point_3</i> <i>p</i> , <i>Kernel::Point_3</i> <i>q</i> , <i>Kernel::Point_3</i> <i>r</i> , <i>Kernel::Point_3</i> <i>s</i> , <i>Kernel::Point_3</i> <i>t</i>)
----------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

returns the relative position of point t to the oriented sphere defined by p, q, r and s . The order of the points p, q, r , and s is important, since it determines the orientation of the implicitly constructed sphere. If the points p, q, r and s are positive oriented, positive side is the bounded interior of the sphere.

Precondition: p, q, r and s are not coplanar.

Chapter 3

dD Kernel

Michael Seel

3.1 Introduction

This part of the reference manual covers the higher-dimensional kernel. The kernel contains objects of constant size, such as point, vector, direction, line, ray, segment, circle. With each type comes a set of functions which can be applied to an object of this type. You will typically find access functions (e.g. to the coordinates of a point), tests of the position of a point relative to the object, a function returning the bounding box, the length, or the area of an object, and so on. The CGAL kernel further contains basic operations such as affine transformations, detection and computation of intersections, and distance computations. Note that this section partly recapitulates facts already mentioned for the lower-dimensional kernel.

3.1.1 Robustness

The correctness proof of nearly all geometric algorithms presented in theory papers assumes exact computation with real numbers. This leads to a fundamental problem with the implementation of geometric algorithms. Naively, often the exact real arithmetic is replaced by inexact floating-point arithmetic in the implementation. This often leads to acceptable results for many input data. However, even for the implementation of the simplest geometric algorithms this simplification occasionally does not work. Rounding errors introduced by inaccurate arithmetic may lead to inconsistent decisions, causing unexpected failures for some correct input data. There are many approaches to this problem, one of them is to compute exactly (compute so accurate that all decisions made by the algorithm are exact) which is possible in many cases but more expensive than standard floating-point arithmetic. C. M. Hoffmann [[Hof89a](#), [Hof89b](#)] illustrates some of the problems arising in the implementation of geometric algorithms and discusses some approaches to solve them. A more recent overview is given in [[Sch00](#)]. The exact computation paradigm is discussed by Yap and Dubé [[YD95](#)] and Yap [[Yap97](#)].

In CGAL you can choose the underlying number types and arithmetic. You can use different types of arithmetic simultaneously and the choice can be easily changed, e.g. for testing. So you can choose between implementations with fast but occasionally inexact arithmetic and implementations guaranteeing exact computation and exact results. Of course you have to pay for the exactness in terms of execution time and storage space. See the section on number types in the Support Library for more details on number types and their capabilities and performance.

3.1.2 Genericity

To increase generic usage of objects and predicates the higher-dimensional kernel makes heavy use of iterator ranges as defined in the STL for modelling tuples. Iterators conceptualize C++ pointers.

For an iterator range $[first, last)$ we define $T = tuple [first, last)$ as the ordered tuple $(T[0], T[1], \dots, T[d-1])$ where $S[i] = * + +^{(i)}first$ (the element obtained by i times forwarding the iterator by operator $++$ and then dereferencing it to get the value to which it points). We write $d = size [first, last)$ and $S = set [first, last)$ to denote the unordered set of elements of the corresponding tuple.

This extends the syntax of random access iterators to input iterators. If we index the tuple as above then we require that $++^{(d+1)}first = last$.

3.2 Kernel Representations

Our object of study is the d -dimensional affine Euclidean space, where d is a parameter of our geometry. Objects in that space are sets of points. A common way to represent the points is the use of Cartesian coordinates, which assumes a reference frame (an origin and d orthogonal axes). In that framework, a point is represented by a d -tuple $(c_0, c_1, \dots, c_{d-1})$, and so are vectors in the underlying linear space. Each point is represented uniquely by such Cartesian coordinates.

Another way to represent points is by homogeneous coordinates. In that framework, a point is represented by a $(d+1)$ -tuple (h_0, h_1, \dots, h_d) . Via the formulae $c_i = h_i/h_d$, the corresponding point with Cartesian coordinates $(c_0, c_1, \dots, c_{d-1})$ can be computed. Note that homogeneous coordinates are not unique. For $\lambda \neq 0$, the tuples (h_0, h_1, \dots, h_d) and $(\lambda \cdot h_0, \lambda \cdot h_1, \dots, \lambda \cdot h_d)$ represent the same point. For a point with Cartesian coordinates $(c_0, c_1, \dots, c_{d-1})$ a possible homogeneous representation is $(c_0, c_1, \dots, c_{d-1}, 1)$. Homogeneous coordinates in fact allow to represent objects in a more general space, the projective space \mathbb{P}_d . In CGAL, we do not compute in projective geometry. Rather, we use homogeneous coordinates to avoid division operations, since the additional coordinate can serve as a common denominator.

3.2.1 Genericity through Parameterization

Almost all the kernel objects (and the corresponding functions) are templates with a parameter that allows the user to choose the representation of the kernel objects. A type that is used as an argument for this parameter must fulfill certain requirements on syntax and semantics. The list of requirements defines an abstract kernel concept. In CGAL such a kernel concept is often also called a *representation class* and denoted by R . A representation class provides the actual implementations of the kernel objects. For all kernel objects $Kernel_object$, the types $CGAL::Kernel_object<R>$ and $R::Kernel_object$ are identical.

CGAL offers two families of concrete models for the concept representation class, one based on the Cartesian representation of points and one based on the homogeneous representation of points. The interface of the kernel objects is designed such that it works well with both Cartesian and homogeneous representation, for example, points have a constructor with a range of coordinates plus a common denominator (the $d+1$ homogeneous coordinates of the point). The common interfaces parameterized with a representation class allow one to develop code independent of the chosen representation. We said “families” of models, because both families are parameterized too. A user can choose the number type used to represent the coordinates and the linear algebra module used to calculate the result of predicates and constructions.

For reasons that will become evident later, a representation class provides two typenames for number types,

namely $R::FT$ and $R::RT$ and one typename for the linear algebra module $R::LA$.¹ The type $R::FT$ must fulfill the requirements on what is called a *field type* in CGAL. This roughly means that $R::FT$ is a type for which operations $+$, $-$, $*$ and $/$ are defined with semantics (approximately) corresponding to those of a field in a mathematical sense. Note that, strictly speaking, the built-in type *int* does not fulfill the requirements on a field type, since *ints* correspond to elements of a ring rather than a field, especially operation $/$ is not the inverse of $*$. The requirements on the type $R::RT$ are weaker. This type must fulfill the requirements on what is called an *Euclidean ring type* in CGAL. This roughly means that $R::RT$ is a type for which operations $+$, $-$, $*$ are defined with semantics (approximately) corresponding to those of a ring in a mathematical sense. A very limited division operation $/$ must be available as well. It must work for exact (i.e., no remainder) integer divisions only. Furthermore, both number types should fulfill CGAL's requirements on a number type.

3.2.2 Cartesian Kernel

With `Cartesian_d<FieldNumberType,LinearAlgebra>` you can choose Cartesian representation of coordinates. The type `LinearAlgebra` must be a linear algebra module working on numbers of type `FieldNumberType`. The second parameter defaults to module delivered with the kernel so for short a user can just write `Cartesian_d<FieldNumberType>` when not providing her own linear algebra.

When you choose Cartesian representation you have to declare at least the type of the coordinates. A number type used with the `Cartesian_d` representation class should be a *field type* as described above. Both `Cartesian<FieldNumberType>::FT` and `Cartesian<FieldNumberType>::RT` are mapped to number type `FieldNumberType`. `Cartesian_d<FieldNumberType,LinearAlgebra>::LA` is mapped to the type `LinearAlgebra`. `Cartesian<FieldNumberType>` uses reference counting internally to save copying costs.

3.2.3 Homogeneous Kernel

As we mentioned before, homogeneous coordinates permit to avoid division operations in numerical computations, since the additional coordinate can serve as a common denominator. Avoiding divisions can be useful for exact geometric computation. With `Homogeneous_d<RingNumberType,LinearAlgebra>` you can choose homogeneous representation of coordinates with the kernel objects. As for Cartesian representation you have to declare at the same time the type used to store the homogeneous coordinates. Since the homogeneous representation allows one to avoid the divisions, the number type associated with a homogeneous representation class must be a model for the weaker concept Euclidean ring type only.

The type `LinearAlgebra` must be a linear algebra module working on numbers of type `RingNumberType`. Again the second parameter defaults to module delivered with the kernel so for short one can just write `Homogeneous_d<RingNumberType>` when replacing the default is no issue.

However, some operations provided by this kernel involve division operations, for example computing squared distances or returning a Cartesian coordinate. To keep the requirements on the number type parameter of `Homogeneous` low, the number type `Quotient<RingNumberType>` is used instead. This number type turns a ring type into a field type. It maintains numbers as quotients, i.e. a numerator and a denominator. Thereby, divisions are circumvented. With `Homogeneous_d<RingNumberType>`, `Homogeneous_d<RingNumberType>::FT` is equal to `Quotient<RingNumberType>` while `Homogeneous_d<RingNumberType>::RT` is equal to `RingNumberType`. `Homogeneous_d<RingNumberType,LinearAlgebra>::LA` is mapped to the type `LinearAlgebra`.

¹The double colon `::` is the C++ scope operator.

3.2.4 Naming conventions

The use of representation classes not only avoids problems, it also makes all CGAL classes very uniform. They **always** consist of:

1. The *capitalized base name* of the geometric object, such as *Point*, *Segment*, *Triangle*.
2. Followed by *_d*.
3. A *representation class* as parameter, which itself is parameterized with a number type, such as *Cartesian_d<double>* or *Homogeneous_d<leda_integer>*.

3.2.5 Kernel as a Traits Class

Algorithms and data structures in the basic library of CGAL are parameterized by a traits class that subsumes the objects on which the algorithm or data structure operates as well as the operations to do so. For most of the algorithms and data structures in the basic library you can use a kernel as a traits class. For some algorithms you even do not have to specify the kernel; it is detected automatically using the types of the geometric objects passed to the algorithm. In some other cases, the algorithms or data structures needs more than is provided by a kernel. In these cases, a kernel can not be used as a traits class.

3.2.6 Choosing a Kernel

If you start with integral Cartesian coordinates, many geometric computations will involve integral numerical values only. Especially, this is true for geometric computations that evaluate only predicates, which are tantamount to determinant computations. Examples are triangulation of point sets and convex hull computation.

The dimension d of our affine space determines the dimension of the matrix computations in the mathematical evaluation of predicates. As rounding errors accumulate fast the homogeneous representation used with multi-precision integers is the kernel of choice for well-behaved algorithms. Note, that unless you use an arbitrary precision integer type, incorrect results might arise due to overflow.

If new points are to be constructed, for example the intersection point of two lines, computation of Cartesian coordinates usually involves divisions, so you need to use a field type with Cartesian representation or have to switch to homogeneous representation. *double* is a possible, but imprecise field type. You can also put any ring type into *Quotient* to get a field type and put it into *Cartesian*, but you better put the ring type into *Homogeneous*. *leda_rational* and *leda_real* are valid field types, too.

Still other people will prefer the built-in type *double*, because they need speed and can live with approximate results, or even algorithms that, from time to time, crash or compute incorrect results due to accumulated rounding errors.

3.2.7 Inclusion of Header Files

You need just to include a representation class to obtain the geometric objects of the kernel that you would like to use with the representation class, i.e., *CGAL/Cartesian_d.h* or *CGAL/Homogeneous_d.h*

3.3 Kernel Geometry

3.3.1 Points and Vectors

In CGAL, we strictly distinguish between points, vectors and directions. A *point* is a point in the Euclidean space \mathbb{E}^d , a *vector* is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2 in the vector space \mathbb{R}^d , and a *direction* is a vector where we forget about its length. They are different mathematical concepts. For example, they behave different under affine transformations and an addition of two points is meaningless in affine geometry. By putting them in different classes we not only get cleaner code, but also type checking by the compiler which avoids ambiguous expressions. Hence, it pays twice to make this distinction.

CGAL defines a symbolic constant *ORIGIN* of type *Origin* which denotes the point at the origin. This constant is used in the conversion between points and vectors. Subtracting it from a point p results in the locus vector of p .

```
double coord[] = {1.0, 1.0, 1.0, 1.0};
Point_d< Cartesian_d<double> > p(4, coord, coord+4), q(4);
Vector_d< Cartesian_d<double> > v(4);
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

In order to obtain the point corresponding to a vector v you simply have to add v to *ORIGIN*. If you want to determine the point q in the middle between two points p_1 and p_2 , you can write²

```
q = p_1 + (p_2 - p_1) / 2.0;
```

Note that these constructions do not involve any performance overhead for the conversion with the currently available representation classes.

3.3.2 Kernel Objects

Besides points (*Point_d<R>*), vectors (*Vector_d<R>*), and directions (*Direction_d<R>*), CGAL provides lines, rays, segments, hyperplanes, and spheres.

Lines (*Line_d<R>*) in CGAL are oriented. A ray (*Ray_d<R>*) is a semi-infinite interval on a line, and this line is oriented from the finite endpoint of this interval towards any other point in this interval. A segment (*Segment_d<R>*) is a bounded interval on a directed line, and the endpoints are ordered so that they induce the same direction as that of the line.

Hyperplanes are affine subspaces of dimension $d - 1$ in \mathbb{E}^d , passing through d points. Hyperplanes are oriented and partition space into a positive side and a negative side. In CGAL, there are no special classes for halfspaces. Halfspaces are supposed to be represented by oriented hyperplanes. All kernel objects are equality comparable via *operator==* and *operator!=*. For those oriented objects whose orientation can be reversed (segments, lines, hyperplanes, spheres) there is also a global function *weak_equality* that allows to test for point set equality disregarding the orientation.

²you might call *midpoint(p_1, p_2)* instead

3.3.3 Orientation and Relative Position

Geometric objects in CGAL have member functions that test the position of a point relative to the object. Full dimensional objects and their boundaries are represented by the same type, e.g. halfspaces and hyperplanes are not distinguished, neither are balls and spheres. Such objects split the ambient space into two full-dimensional parts, a bounded part and an unbounded part (e.g. spheres), or two unbounded parts (e.g. hyperplanes). By default these objects are oriented, i.e., one of the resulting parts is called the positive side, the other one is called the negative side. Both of these may be unbounded.

For these objects there is a function *oriented_side()* that determines whether a test point is on the positive side, the negative side, or on the oriented boundary. This function returns a value of type *Oriented_side*.

Those objects that split the space in a bounded and an unbounded part, have a member function *bounded_side()* with return type *Bounded_side*.

If an object is lower dimensional, e.g. a segment in d -dimensional space, there is only a test whether a point belongs to the object or not. This member function, which takes a point as an argument and returns a boolean value, is called *has_on()*

3.4 Predicates and Constructions

3.4.1 Predicates

Predicates are at the heart of a geometry kernel. They are basic units for the composition of geometric algorithms and encapsulate decisions. Hence their correctness is crucial for the control flow and hence for the correctness of an implementation of a geometric algorithm. CGAL uses the term predicate in a generalized sense. Not only components returning a Boolean value are called predicates but also components returning an enumeration type like a *Comparison_result* or an *Orientation*. We say components, because predicates are implemented both as functions and function objects (also called functors and provided by a kernel class).

CGAL provides predicates for the orientation of point sets (*orientation*), for comparing points according to some given order, especially for comparing Cartesian coordinates (e.g. *lexicographically_xy_smaller*), in-sphere tests, and predicates to compare distances.

3.4.2 Constructions

Functions and function objects that generate objects that are neither of type *bool* nor enum types are called constructions. Constructions involve computation of new numerical values and may be imprecise due to rounding errors unless a kernel with an exact number type is used.

Affine transformations (*Aff_transformation_d<R>*) allow to generate new object instances under arbitrary affine transformations. These transformations include translations, rotations (within planes) and scaling. Most of the geometric objects in a kernel have a member function *transform(Aff_transformation t)* which applies the transformation to the object instance.

CGAL also provides a set of functions that detect or compute the intersection between objects and functions to calculate their squared distance. Moreover, some member functions of kernel objects are constructions.

So there are routines that compute the square of the Euclidean distance, but no routines that compute the distance itself. Why? First of all, the two values can be derived from each other quite easily (by taking the square root

or taking the square). So, supplying only the one and not the other is only a minor inconvenience for the user. Second, often either value can be used. This is for example the case when (squared) distances are compared. Third, the library wants to stimulate the use of the squared distance instead of the distance. The squared distance can be computed in more cases and the computation is cheaper. We do this by not providing the perhaps more natural routine, The problem of a distance routine is that it needs the *sqrt* operation. This has two drawbacks:

- The *sqrt* operation can be costly. Even if it is not very costly for a specific number type and platform, avoiding it is always cheaper.
- There are number types on which no *sqrt* operation is defined, especially integer types and rationals.

3.4.3 Intersection and Polymorphic Return Values

Intersections on kernel objects currently cover only those objects that are part of flats (*Segment_d*<*R*>, *Ray_d*<*R*>, *Line_c*<*R*>, and *Hyperplane_d*<*R*>). For any pair of objects *o1*, *o2* of these types the operation *intersection(o1,o2)* returns a polymorphic object that wraps the result of the intersection operation.

The class *Object* provides the polymorphic abstraction. An object *obj* of type *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make_object()*. This encapsulation mechanism requires the use of *assign* to unwrap the encapsulated class.

Example

In the following example, the object type is used as a return value for the intersection computation, as there are possibly different return values.

```
Point_d< Cartesian_d<double> > p;
Segment_d< Cartesian_d<double> > s, s1, s2;
std::cin >> s1 >> s2;
Object obj = intersection(s1, s2);
if ( assign(p, obj) ) {
    /* do something with p */
} else if ( (assign(s, obj) ) {
    /* do something with s */
}
/* there was no intersection */
```

3.4.4 Constructive Predicates

For testing where a point *p* lies with respect to a hyperplane defined by an array *P* of points *p*₁, ... , *p*_{*d*}, one may be tempted to construct the hyperplane *Hyperplane_d*<*R*>(*d*,*P*,*P*+*d*) and use the method *oriented_side(p)*. This may pay off if many tests with respect to the plane are made. Nevertheless, unless the number type is exact, the constructed plane is only approximated, and round-off errors may lead *oriented_side(p)* to return an orientation which is different from the orientation of *p*₁, ... , *p*_{*d*}, *p*.

In CGAL, we provide predicates in which such geometric decisions are made directly with a reference to the input points in *P* without an intermediary object like a plane. For the above test, the recommended way to get the result is to use *orientation(P',P'+d)*, where *P'* is an array containing the points *p*₁, ... , *p*_{*d*}, *p*.

For exact number types like *leda_real*, the situation is different. If several tests are to be made with the same plane, it pays off to construct the plane and to use *oriented_side(p)*.

3.5 Linear Algebra Concepts and Classes

LinearAlgebraTraits_d

Definition

The data type *LinearAlgebraTraits_d* encapsulates two classes *Matrix*, *Vector* and many functions of basic linear algebra. An instance of data type *Matrix* is a matrix of variables of type *NT*. Accordingly, *Vector* implements vectors of variables of type *NT*. Most functions of linear algebra are *checkable*, i.e., the programs can be asked for a proof that their output is correct. For example, if the linear system solver declares a linear system $Ax = b$ unsolvable it also returns a vector c such that $c^T A = 0$ and $c^T b \neq 0$.

Types

LinearAlgebraTraits_d::NT the number type of the components.

LinearAlgebraTraits_d::Vector the vector type.

LinearAlgebraTraits_d::Matrix the matrix type.

Operations

static Matrix *LA.transpose(Matrix M)*

returns M^T (a $M.column_dimension() \times M.column_dimension()$ - matrix).

static bool *LA.inverse(Matrix M, Matrix& I, NT& D, Vector& c)*

determines whether M has an inverse. It also computes either the inverse as $(1/D) \cdot I$ or when no inverse exists, a vector c such that $c^T \cdot M = 0$.

Precondition: M is square.

static Matrix *LA.inverse(Matrix M, NT& D)*

returns the inverse matrix of M . More precisely, $1/D$ times the matrix returned is the inverse of M .

Precondition: $determinant(M) \neq 0$.

Precondition: M is square.

static bool *LA.linear_solver(Matrix M, Vector b, Vector& x, NT& D)*

as above, but without the witness *c*
Precondition: M.row_dimension() = b.dimension().

static bool *LA.is_solvable(Matrix M, Vector b)*

determines whether the system $M \cdot x = b$ is solvable
Precondition: M.row_dimension() = b.dimension().

static bool *LA.homogeneous_linear_solver(Matrix M, Vector& x)*

determines whether the homogeneous linear system $M \cdot x = 0$ has a non - trivial solution. If yes, then *x* is such a solution.

static int *LA.homogeneous_linear_solver(Matrix M, Matrix& spanning_vecs)*

determines the solution space of the homogeneous linear system $M \cdot x = 0$. It returns the dimension of the solution space. Moreover the columns of *spanning_vecs* span the solution space.

static int *LA.independent_columns(Matrix M, std::vector<int>& columns)*

returns the indices of a maximal subset of independent columns of *M*.

static int *LA.rank(Matrix M)*

returns the rank of matrix *M*

Vector

Definition

An instance of data type *Vector* is a vector of variables of number type *NT*. Together with the type *Matrix* it realizes the basic operations of linear algebra.

Types

<i>Vector::NT</i>	the ring type of the components.
<i>Vector::iterator</i>	the iterator type for accessing components.
<i>Vector::const_iterator</i>	the const iterator type for accessing components.

Creation

<i>Vector</i> <i>v</i> ;	creates an instance <i>v</i> of type <i>Vector</i> .
<i>Vector</i> <i>v</i> (<i>int d</i>);	creates an instance <i>v</i> of type <i>Vector</i> . <i>v</i> is initialized to a vector of dimension <i>d</i> .
<i>Vector</i> <i>v</i> (<i>int d</i> , <i>NT x</i>);	creates an instance <i>v</i> of type <i>Vector</i> . <i>v</i> is initialized to a vector of dimension <i>d</i> with entries <i>x</i> .
<i>template</i> <class <i>Forward_iterator</i> > <i>Vector</i> <i>v</i> (<i>Forward_iterator first</i> , <i>Forward_iterator last</i>);	
	creates an instance <i>v</i> of type <i>Vector</i> ; <i>v</i> is initialized to the vector with entries set [<i>first</i> , <i>last</i>).
	<i>Requirement: Forward_iterator</i> has value type <i>NT</i> .

Operations

<i>int</i>	<i>v.dimension()</i>	returns the dimension of <i>v</i> .
<i>bool</i>	<i>v.is_zero()</i>	returns true iff <i>v</i> is the zero vector.
<i>NT&</i>	<i>v[int i]</i>	returns the <i>i</i> -th component of <i>v</i> . <i>Precondition:</i> $0 \leq i \leq v.dimension() - 1$.
<i>iterator</i>	<i>v.begin()</i>	iterator to the first component.
<i>iterator</i>	<i>v.end()</i>	iterator beyond the last component.

The same operations *begin()*, *end()* exist for *const_iterator*.

<i>Vector</i>	$v + vI$	Addition. <i>Precondition:</i> $v.dimension() == vI.dimension()$.
<i>Vector</i>	$v - vI$	Subtraction. <i>Precondition:</i> $v.dimension() = vI.dimension()$.
<i>NT</i>	$v * vI$	Inner Product. <i>Precondition:</i> $v.dimension() = vI.dimension()$.
<i>Vector</i>	$-v$	Negation.
<i>Vector&</i>	$v += vI$	Addition plus assignment. <i>Precondition:</i> $v.dimension() == vI.dimension()$.
<i>Vector&</i>	$v -= vI$	Subtraction plus assignment. <i>Precondition:</i> $v.dimension() == vI.dimension()$.
<i>Vector&</i>	$v *= NT\ s$	Scalar multiplication plus assignment.
<i>Vector&</i>	$v /= NT\ s$	Scalar division plus assignment.
<i>Vector</i>	$NT\ r * v$	Componentwise multiplication with number r .
<i>Vector</i>	$v * NT\ r$	Componentwise multiplication with number r .

Matrix

Definition

An instance of data type *Matrix* is a matrix of variables of number type *NT*. The types *Matrix* and *Vector* together realize many functions of basic linear algebra.

Types

<i>Matrix:: NT</i>	the ring type of the components.
<i>Matrix:: iterator</i>	bidirectional iterator for accessing all components row-wise.
<i>Matrix:: row_iterator</i>	random access iterator for accessing row entries.
<i>Matrix:: column_iterator</i>	random access iterator for accessing column entries.

There also constant versions of the above iterators: *const_iterator*, *row_const_iterator*, and *column_const_iterator*.

<i>Matrix:: Identity</i>	a tag class for identity initialization
<i>Matrix:: Vector</i>	the vector type used.

Creation

<i>Matrix M</i> ;	creates an instance <i>M</i> of type <i>Matrix</i> .
<i>Matrix M</i> (<i>int n</i>);	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $n \times n$ initialized to the zero matrix.
<i>Matrix M</i> (<i>int m</i> , <i>int n</i>);	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $m \times n$ initialized to the zero matrix.
<i>Matrix M</i> (<i>std::pair<int,int> p</i>);	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $p.first \times p.second$ initialized to the zero matrix.
<i>Matrix M</i> (<i>int n</i> , <i>Identity</i> , <i>NT x</i> = <i>NT(1)</i>);	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $n \times n$ initialized to the identity matrix (times <i>x</i>).
<i>Matrix M</i> (<i>int m</i> , <i>int n</i> , <i>NT x</i>);	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $m \times n$ initialized to the matrix with <i>x</i> entries.

```
template <class Forward_iterator>
```

```
Matrix M( Forward_iterator first, Forward_iterator last);
```

creates an instance M of type *Matrix*. Let S be the ordered set of n column-vectors of common dimension m as given by the iterator range $[first, last)$. M is initialized to an $m \times n$ matrix with the columns as specified by S .

Precondition: *Forward_iterator* has a value type V from which we require to provide a iterator type $V::const_iterator$, to have $V::value_type == NT$.

Note that *Vector* or $std::vector<NT>$ fulfill these requirements.

```
Matrix M( std::vector< Vector > A);
```

creates an instance M of type *Matrix*. Let A be an array of n column-vectors of common dimension m . M is initialized to an $m \times n$ matrix with the columns as specified by A .

Operations

<i>int</i>	<i>M.row_dimension()</i>	returns n , the number of rows of M .
<i>int</i>	<i>M.column_dimension()</i>	returns m , the number of columns of M .
<i>std::pair<int,int></i>	<i>M.dimension()</i>	returns (m, n) , the dimension pair of M .
<i>Vector</i>	<i>M.row(int i)</i>	returns the i -th row of M (an m - vector). <i>Precondition:</i> $0 \leq i \leq m - 1$.
<i>Vector</i>	<i>M.column(int i)</i>	returns the i -th column of M (an n - vector). <i>Precondition:</i> $0 \leq i \leq n - 1$.
<i>NT&</i>	<i>M(int i, int j)</i>	returns $M_{i,j}$. <i>Precondition:</i> $0 \leq i \leq m - 1$ and $0 \leq j \leq n - 1$.
<i>void</i>	<i>M.swap_rows(int i, int j)</i>	swaps rows i and j . <i>Precondition:</i> $0 \leq i \leq m - 1$ and $0 \leq j \leq m - 1$.
<i>void</i>	<i>M.swap_columns(int i, int j)</i>	swaps columns i and j . <i>Precondition:</i> $0 \leq i \leq n - 1$ and $0 \leq j \leq n - 1$.
<i>row_iterator</i>	<i>M.row_begin(int i)</i>	an iterator pointing to the first entry of the i th row. <i>Precondition:</i> $0 \leq i \leq m - 1$.
<i>row_iterator</i>	<i>M.row_end(int i)</i>	an iterator pointing beyond the last entry of the i th row. <i>Precondition:</i> $0 \leq i \leq m - 1$.

<i>column_iterator</i>	<i>M.column_begin(int i)</i>	an iterator pointing to the first entry of the <i>i</i> th column. <i>Precondition:</i> $0 \leq i \leq n - 1$.
<i>column_iterator</i>	<i>M.column_end(int i)</i>	an iterator pointing beyond the last entry of the <i>i</i> th column. <i>Precondition:</i> $0 \leq i \leq n - 1$.
<i>iterator</i>	<i>M.begin()</i>	an iterator pointing to the first entry of <i>M</i> .
<i>iterator</i>	<i>M.end()</i>	an iterator pointing beyond the last entry of <i>M</i> .

The same operations exist for *row_const_iterator*, *column_const_iterator* and *const_iterator*.

<i>bool</i>	<i>M == M1</i>	Test for equality.
<i>bool</i>	<i>M != M1</i>	Test for inequality.

Arithmetic Operators

<i>Matrix</i>	<i>M + M1</i>	Addition. <i>Precondition:</i> <i>M.row_dimension() == M1.row_dimension()</i> and <i>M.column_dimension() == M1.column_dimension()</i> .
<i>Matrix</i>	<i>M - M1</i>	Subtraction. <i>Precondition:</i> <i>M.row_dimension() == M1.row_dimension()</i> and <i>M.column_dimension() == M1.column_dimension()</i> .
<i>Matrix</i>	<i>-M</i>	Negation.
<i>Matrix</i>	<i>M * M1</i>	Multiplication. <i>Precondition:</i> <i>M.column_dimension() == M1.row_dimension()</i> .
<i>Vector</i>	<i>M * Vector vec</i>	Multiplication with vector. <i>Precondition:</i> <i>M.column_dimension() == vec.dimension()</i> .
<i>Matrix</i>	<i>NT x * M</i>	Multiplication of every entry with <i>x</i> .
<i>Matrix</i>	<i>M * NT x</i>	Multiplication of every entry with <i>x</i> .

CGAL::Linear_algebraCd<FT>

Definition

The class *Linear_algebraCd*<FT> serves as the default traits class for the LA parameter of *CGAL::Cartesian_d*<FT,LA>. It implements linear algebra for field number types *FT*.

```
#include <CGAL/Linear_algebraCd.h>
```

Is Model for the Concepts

LinearAlgebraTraits_d page [437](#)

Requirements

FT must be a field number type.

Operations

Fits all operation requirements of the concept.

CGAL::Linear_algebraHd<RT>

Definition

The class *Linear_algebraHd*<*RT*> serves as the default traits class for the LA parameter of *CGAL::Homogeneous_d*<*RT*,*LA*>. It implements linear algebra for Euclidean ring number types *RT*.

```
#include <CGAL/Linear_algebraHd.h>
```

Is Model for the Concepts

LinearAlgebraTraits_d page [437](#)

Requirements

To make a ring number type *RT* work with this class it has to provide a division *operator/* with remainder.

Operations

Fits all operation requirements of the concept.

3.6 Kernel Objects

CGAL::Point_d<Kernel>

Definition

An instance of data type *Point_d<Kernel>* is a point of Euclidean space in dimension d . A point $p = (p_0, \dots, p_{d-1})$ in d -dimensional space can be represented by homogeneous coordinates (h_0, h_1, \dots, h_d) of number type RT such that $p_i = h_i/h_d$, which is of type FT . The homogenizing coordinate h_d is positive.

We call p_i , $0 \leq i < d$ the i -th Cartesian coordinate and h_i , $0 \leq i \leq d$, the i -th homogeneous coordinate. We call d the dimension of the point.

Types

Point_d<Kernel>:: RT the ring type.

Point_d<Kernel>:: FT the field type.

Point_d<Kernel>:: LA the linear algebra layer.

Point_d<Kernel>:: Cartesian_const_iterator
a read-only iterator for the Cartesian coordinates.

Point_d<Kernel>:: Homogeneous_const_iterator
a read-only iterator for the homogeneous coordinates.

Creation

Point_d<Kernel> p; introduces a variable p of type *Point_d<Kernel>*.

Point_d<Kernel> p(int d, Origin);
introduces a variable p of type *Point_d<Kernel>* in d -dimensional space, initialized to the origin.

template <class InputIterator>

Point_d<Kernel> p(int d, InputIterator first, InputIterator last);

introduces a variable p of type $Point_d<Kernel>$ in dimension d . If $size\ [first, last) == d$ this creates a point with Cartesian coordinates $set\ [first, last)$. If $size\ [first, last) == p+1$ the range specifies the homogeneous coordinates $H = set\ [first, last) = (\pm h_0, \pm h_1, \dots, \pm h_d)$ where the sign chosen is the sign of h_d .

Precondition: d is nonnegative, $[first, last)$ has d or $d+1$ elements where the last has to be non-zero.

Requirement: The value type of $InputIterator$ is RT .

template <class InputIterator>

Point_d<Kernel> p(int d, InputIterator first, InputIterator last, RT D);

introduces a variable p of type $Point_d<Kernel>$ in dimension d initialized to the point with homogeneous coordinates as defined by $H = set\ [first, last)$ and $D: (\pm H[0], \pm H[1], \dots, \pm H[d-1], \pm D)$. The sign chosen is the sign of D .

Precondition: D is non-zero, the iterator range defines a d -tuple of RT .

Requirement: The value type of $InputIterator$ is RT .

Point_d<Kernel> p(RT x, RT y, RT w = 1);

introduces a variable p of type $Point_d<Kernel>$ in 2-dimensional space.

Precondition: $w \neq 0$.

Point_d<Kernel> p(RT x, RT y, RT z, RT w);

introduces a variable p of type $Point_d<Kernel>$ in 3-dimensional space.

Precondition: $w \neq 0$.

Operations

<i>int</i>	<i>p.dimension()</i>	returns the dimension of p .
<i>FT</i>	<i>p.cartesian(int i)</i>	returns the i -th Cartesian coordinate of p . <i>Precondition:</i> $0 \leq i < d$.
<i>FT</i>	<i>p[int i]</i>	returns the i -th Cartesian coordinate of p . <i>Precondition:</i> $0 \leq i < d$.
<i>RT</i>	<i>p.homogeneous(int i)</i>	returns the i -th homogeneous coordinate of p . <i>Precondition:</i> $0 \leq i \leq d$.
<i>Cartesian_const_iterator</i>	<i>p.cartesian_begin()</i>	returns an iterator pointing to the zeroth Cartesian coordinate p_0 of p .

<i>Cartesian_const_iterator</i>	<i>p.cartesian_end()</i>	returns an iterator pointing beyond the last Cartesian coordinate of <i>p</i> .
---------------------------------	--------------------------	---------------------------------------------------------------------------------

Homogeneous_const_iterator

p.homogeneous_begin()

returns an iterator pointing to the zeroth homogeneous coordinate h_0 of *p*.

Homogeneous_const_iterator

p.homogeneous_end()

returns an iterator pointing beyond the last homogeneous coordinate of *p*.

Point_d<Kernel>

p.transform(Aff_transformation_d<Kernel> t)

returns $t(p)$.

Arithmetic Operators, Tests and IO

Vector_d<Kernel>

p - Origin o

returns the vector $p - O$.

Vector_d<Kernel>

p - q

returns $p - q$.
Precondition: $p.dimension() == q.dimension()$.

Point_d<Kernel>

p + Vector_d<Kernel> v

returns $p + v$.
Precondition: $p.dimension() == v.dimension()$.

Point_d<Kernel>

p - Vector_d<Kernel> v

returns $p - v$.
Precondition: $p.dimension() == v.dimension()$.

Point_d<Kernel>&

p += Vector_d<Kernel> v

adds v to p .

Precondition: $p.dimension() == v.dimension()$.

Point_d<Kernel>&

p -= Vector_d<Kernel> v

subtracts v from p .

Precondition: $p.dimension() == v.dimension()$.

bool $p == Origin$ returns true if p is the origin.

Downward compatibility

We provide operations of the lower dimensional interface $x()$, $y()$, $z()$, $hx()$, $hy()$, $hz()$, $hw()$.

Implementation

Points are implemented by arrays of RT items. All operations like creation, initialization, tests, point - vector arithmetic, input and output on a point p take time $O(p.dimension())$. $dimension()$, coordinate access and conversions take constant time. The space requirement for points is $O(p.dimension())$.

CGAL::Vector_d<Kernel>

Definition

An instance of data type *Vector_d<Kernel>* is a vector of Euclidean space in dimension d . A vector $r = (r_0, \dots, r_{d-1})$ can be represented in homogeneous coordinates (h_0, \dots, h_d) of number type RT , such that $r_i = h_i/h_d$ which is of type FT . We call the r_i 's the Cartesian coordinates of the vector. The homogenizing coordinate h_d is positive.

This data type is meant for use in computational geometry. It realizes free vectors as opposed to position vectors (type *Point_d*). The main difference between position vectors and free vectors is their behavior under affine transformations, e.g., free vectors are invariant under translations.

Types

Vector_d<Kernel>::RT the ring type.

Vector_d<Kernel>::FT the field type.

Vector_d<Kernel>::LA the linear algebra layer.

Vector_d<Kernel>::Cartesian_const_iterator
a read-only iterator for the Cartesian coordinates.

Vector_d<Kernel>::Homogeneous_const_iterator
a read-only iterator for the homogeneous coordinates.

Vector_d<Kernel>::Base_vector
construction tag.

Creation

Vector_d<Kernel> v; introduces a variable v of type *Vector_d<Kernel>*.

Vector_d<Kernel> v(int d, Null_vector);
introduces the zero vector v of type *Vector_d<Kernel>* in d -dimensional space.
For the creation flag *CGAL::NULL_VECTOR* can be used.

template <class InputIterator>

Vector_d<Kernel> v(int d, InputIterator first, InputIterator last);

introduces a variable v of type *Vector_d<Kernel>* in dimension d . If *size [first,last) == d* this creates a vector with Cartesian coordinates *set [first,last)*. If *size [first,last) == p+1* the range specifies the homogeneous coordinates $H = \text{set } [first, last) = (\pm h_0, \pm h_1, \dots, \pm h_d)$ where the sign chosen is the sign of h_d .

Precondition: d is nonnegative, *[first,last)* has d or $d+1$ elements where the last has to be non-zero.

Requirement: The value type of *InputIterator* is *RT*.

template <class InputIterator>

Vector_d<Kernel> v(int d, InputIterator first, InputIterator last, RT D);

introduces a variable v of type *Vector_d<Kernel>* in dimension d initialized to the vector with homogeneous coordinates as defined by $H = \text{set } [first, last)$ and $D: (\pm H[0], \pm H[1], \dots, \pm H[d-1], \pm D)$. The sign chosen is the sign of D .

Precondition: D is non-zero, the iterator range defines a d -tuple of *RT*.

Requirement: The value type of *InputIterator* is *RT*.

Vector_d<Kernel> v(int d, Base_vector, int i);

returns a variable v of type *Vector_d<Kernel>* initialized to the i -th base vector of dimension d .

Precondition: $0 \leq i < d$.

Vector_d<Kernel> v(RT x, RT y, RT w = 1);

introduces a variable v of type *Vector_d<Kernel>* in 2-dimensional space.

Precondition: $w \neq 0$.

Vector_d<Kernel> v(RT x, RT y, RT z, RT w);

introduces a variable v of type *Vector_d<Kernel>* in 3-dimensional space.

Precondition: $w \neq 0$.

Operations

<i>int</i>	<i>v.dimension()</i>	returns the dimension of v .
<i>FT</i>	<i>v.cartesian(int i)</i>	returns the i -th Cartesian coordinate of v . <i>Precondition:</i> $0 \leq i < d$.
<i>FT</i>	<i>v[int i]</i>	returns the i -th Cartesian coordinate of v . <i>Precondition:</i> $0 \leq i < d$.
<i>RT</i>	<i>v.homogeneous(int i)</i>	returns the i -th homogeneous coordinate of v . <i>Precondition:</i> $0 \leq i \leq d$.

<i>FT</i>	<i>v.squared_length()</i>	returns the square of the length of <i>v</i> .
<i>Cartesian_const_iterator</i>	<i>v.cartesian_begin()</i>	returns an iterator pointing to the zeroth Cartesian coordinate of <i>v</i> .
<i>Cartesian_const_iterator</i>	<i>v.cartesian_end()</i>	returns an iterator pointing beyond the last Cartesian coordinate of <i>v</i> .
<i>Homogeneous_const_iterator</i>	<i>v.homogeneous_begin()</i>	returns an iterator pointing to the zeroth homogeneous coordinate of <i>v</i> .
<i>Homogeneous_const_iterator</i>	<i>v.homogeneous_end()</i>	returns an iterator pointing beyond the last homogeneous coordinate of <i>v</i> .
<i>Direction_d<Kernel></i>	<i>v.direction()</i>	returns the direction of <i>v</i> .
<i>Vector_d<Kernel></i>	<i>v.transform(Aff_transformation_d<Kernel> t)</i>	returns $t(v)$.

Arithmetic Operators, Tests and IO

<i>Vector_d<Kernel>&</i>	<i>v *= RT n</i>	multiplies all Cartesian coordinates by <i>n</i> .
<i>Vector_d<Kernel>&</i>	<i>v *= FT r</i>	multiplies all Cartesian coordinates by <i>r</i> .
<i>Vector_d<Kernel></i>	<i>v / RT n</i>	returns the vector with Cartesian coordinates $v_i/n, 0 \leq i < d$.
<i>Vector_d<Kernel></i>	<i>v / FT r</i>	returns the vector with Cartesian coordinates $v_i/r, 0 \leq i < d$.
<i>Vector_d<Kernel>&</i>	<i>v /= RT n</i>	divides all Cartesian coordinates by <i>n</i> .
<i>Vector_d<Kernel>&</i>	<i>v /= FT r</i>	divides all Cartesian coordinates by <i>r</i> .
<i>FT</i>	<i>v * w</i>	inner product, i.e., $\sum_{0 \leq i < d} v_i w_i$, where v_i and w_i are the Cartesian coordinates of <i>v</i> and <i>w</i> respectively.
<i>Vector_d<Kernel></i>	<i>v + w</i>	returns the vector with Cartesian coordinates $v_i + w_i, 0 \leq i < d$.
<i>Vector_d<Kernel>&</i>	<i>v += w</i>	addition plus assignment.

<i>Vector_d<Kernel></i>	$v - w$	returns the vector with Cartesian coordinates $v_i - w_i, 0 \leq i < d$.
<i>Vector_d<Kernel>&</i>	$v -= w$	subtraction plus assignment.
<i>Vector_d<Kernel></i>	$-v$	returns the vector in opposite direction.
<i>bool</i>	<i>v.is_zero()</i>	returns true if <i>v</i> is the zero vector.

Downward compatibility

We provide all operations of the lower dimensional interface *x()*, *y()*, *z()*, *hx()*, *hy()*, *hz()*, *hw()*.

<i>Vector_d<Kernel></i>	<i>RT n * v</i>	returns the vector with Cartesian coordinates nv_i .
<i>Vector_d<Kernel></i>	<i>FT r * v</i>	returns the vector with Cartesian coordinates $rv_i, 0 \leq i < d$.

Implementation

Vectors are implemented by arrays of variables of type *RT*. All operations like creation, initialization, tests, vector arithmetic, input and output on a vector *v* take time $O(v.dimension())$. coordinate access, *dimension()* and conversions take constant time. The space requirement of a vector is $O(v.dimension())$.

CGAL::Direction_d<Kernel>

Definition

A *Direction_d* is a vector in the d -dimensional vector space where we forget about its length. We represent directions in d -dimensional space as a tuple (h_0, \dots, h_d) of variables of type RT which we call the homogeneous coordinates of the direction. The coordinate h_d must be positive. The Cartesian coordinates of a direction are $c_i = h_i/h_d$ for $0 \leq i < d$, which are of type FT . Two directions are equal if their Cartesian coordinates are positive multiples of each other. Directions are in one-to-one correspondence to points on the unit sphere.

Types

Direction_d<Kernel>::RT the ring type.

Direction_d<Kernel>::FT the field type.

Direction_d<Kernel>::LA the linear algebra layer.

Direction_d<Kernel>::Delta_const_iterator
a read-only iterator for the deltas of *dir*.

Direction_d<Kernel>::Base_direction
construction tag.

Creation

Direction_d<Kernel> dir; introduces a variable *dir* of type *Direction_d<Kernel>*.

Direction_d<Kernel> dir(Vector_d<Kernel> v);
introduces a variable *dir* of type *Direction_d<Kernel>* initialized to the direction of *v*.

template <class InputIterator>
Direction_d<Kernel> dir(int d, InputIterator first, InputIterator last);
introduces a variable *dir* of type *Direction_d<Kernel>* in dimension d with representation tuple *set* $[first, last)$.
Precondition: d is nonnegative, $[first, last)$ has d elements.
Requirement: The value type of *InputIterator* is RT .

Direction_d<Kernel> *dir*(*int d*, *Base_direction*, *int i*);

returns a variable *dir* of type *Direction_d<Kernel>* initialized to the direction of the *i*-th base vector of dimension *d*.
Precondition: $0 \leq i < d$.

Direction_d<Kernel> *dir*(*RT x*, *RT y*);

introduces a variable *dir* of type *Direction_d<Kernel>* in 2-dimensional space.

Direction_d<Kernel> *dir*(*RT x*, *RT y*, *RT z*);

introduces a variable *dir* of type *Direction_d<Kernel>* in 3-dimensional space.

Operations

<i>int</i>	<i>dir.dimension()</i>	returns the dimension of <i>dir</i> .
<i>RT</i>	<i>dir.delta(int i)</i>	returns the <i>i</i> -th component of <i>dir</i> . <i>Precondition</i> : $0 \leq i < d$.
<i>RT</i>	<i>dir[int i]</i>	returns the <i>i</i> -th delta of <i>dir</i> . <i>Precondition</i> : $0 \leq i < d$.
<i>Delta_const_iterator</i>	<i>dir.deltas_begin()</i>	returns an iterator pointing to the first delta of <i>dir</i> .
<i>Delta_const_iterator</i>	<i>dir.deltas_end()</i>	returns an iterator pointing beyond the last delta of <i>dir</i> .
<i>Vector_d<Kernel></i>	<i>dir.vector()</i>	returns a vector pointing in direction <i>dir</i> .
<i>bool</i>	<i>dir.is_degenerate()</i>	returns true iff <i>dir.delta(i)=0</i> for all $0 \leq i < d$.
<i>Direction_d<Kernel></i>	<i>dir.transform(Aff_transformation_d<Kernel> t)</i>	returns <i>t(p)</i> .
<i>Direction_d<Kernel></i>	<i>dir.opposite()</i>	returns the direction opposite to <i>dir</i> .
<i>Direction_d<Kernel></i>	$-dir$	returns the direction opposite to <i>dir</i> .

Downward compatibility

We provide the operations of the lower dimensional interface *dx()*, *dy()*, *dz()*.

Implementation

Directions are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, inversion, input and output on a direction d take time $O(d.dimension())$. $dimension()$, coordinate access and conversion take constant time. The space requirement is $O(d.dimension())$.

CGAL::Line_d<Kernel>

Definition

An instance of data type *Line_d* is an oriented line in *d*-dimensional Euclidean space.

Types

Line_d<Kernel>::R the representation type.

Line_d<Kernel>::RT the ring type.

Line_d<Kernel>::FT the field type.

Line_d<Kernel>::LA the linear algebra layer.

Creation

Line_d<Kernel> l; introduces a variable *l* of type *Line_d<Kernel>*.

Line_d<Kernel> l(Point_d<Kernel> p, Point_d<Kernel> q);

introduces a line through *p* and *q* and oriented from *p* to *q*.

Precondition: *p* and *q* are distinct and have the same dimension.

Line_d<Kernel> l(Point_d<Kernel> p, Direction_d<Kernel> dir);

introduces a line through *p* with direction *dir*.

Precondition: *p.dimension()==dir.dimension()*, *dir* is not degenerate.

Line_d<Kernel> l(Segment_d<Kernel> s);

introduces a variable *l* of type *Line_d<Kernel>* and initializes it to the line through *s.source()* and *s.target()* with direction from *s.source()* to *s.target()*.

Precondition: *s* is not degenerate.

Line_d<Kernel> l(Ray_d<Kernel> r);

introduces a variable *l* of type *Line_d<Kernel>* and initializes it to the line through *r.point(1)* and *r.point(2)*.

Operations

<i>int</i>	<i>l.dimension()</i>	returns the dimension of the ambient space.
<i>Point_d<Kernel></i>	<i>l.point(int i)</i>	returns an arbitrary point on <i>l</i> . It holds that <i>point(i) == point(j)</i> , iff <i>i==j</i> . Furthermore, <i>l</i> is directed from <i>point(i)</i> to <i>point(j)</i> , for all <i>i < j</i> .
<i>Line_d<Kernel></i>	<i>l.opposite()</i>	returns the line (<i>point(2),point(1)</i>) of opposite direction.
<i>Direction_d<Kernel></i>	<i>l.direction()</i>	returns the direction of <i>l</i> .
<i>Line_d<Kernel></i>	<i>l.transform(Aff_transformation_d<Kernel> t)</i>	returns <i>t(l)</i> . Precondition: <i>l.dimension()==t.dimension()</i> .
<i>Line_d<Kernel></i>	<i>l + Vector_d<Kernel> v</i>	returns <i>l+v</i> , i.e., <i>l</i> translated by vector <i>v</i> . Precondition: <i>l.dimension()==v.dimension()</i> .
<i>Point_d<Kernel></i>	<i>l.projection(Point_d<Kernel> p)</i>	returns the point of intersection of <i>l</i> with the hyperplane that is orthogonal to <i>l</i> and that contains <i>p</i> . Precondition: <i>l.dimension()==p.dimension()</i> .
<i>bool</i>	<i>l.has_on(Point_d<Kernel> p)</i>	returns true if <i>p</i> lies on <i>l</i> and false otherwise. Precondition: <i>l.dimension()==p.dimension()</i> .

Non-Member Functions

<i>bool</i>	<i>weak_equality(l1, l2)</i>	Test for equality as unoriented lines. Precondition: <i>l1.dimension()==l2.dimension()</i> .
<i>bool</i>	<i>parallel(l1, l2)</i>	returns true if <i>l1</i> and <i>l2</i> are parallel as unoriented lines and false otherwise. Precondition: <i>l1.dimension()==l2.dimension()</i> .

Implementation

Lines are implemented by a pair of points as an item type. All operations like creation, initialization, tests, direction calculation, input and output on a line *l* take time $O(l.dimension())$. *dimension()*, coordinate and point access, and identity test take constant time. The operations for intersection calculation also take time $O(l.dimension())$. The space requirement is $O(l.dimension())$.

CGAL::Ray_d<Kernel>

Definition

An instance of data type *Ray_d* is a ray in *d*-dimensional Euclidean space. It starts in a point called the source of *r* and it goes to infinity.

Types

Ray_d<Kernel>:: R the representation type.

Ray_d<Kernel>:: RT the ring type.

Ray_d<Kernel>:: FT the field type.

Ray_d<Kernel>:: LA the linear algebra layer.

Creation

Ray_d<Kernel> r; introduces some ray in *d*-dimensional space.

Ray_d<Kernel> r(Point_d<Kernel> p, Point_d<Kernel> q);

introduces a ray through *p* and *q* and starting at *p*.

Precondition: *p* and *q* are distinct and have the same dimension.

Precondition: *p.dimension()==q.dimension()*.

Ray_d<Kernel> r(Point_d<Kernel> p, Direction_d<Kernel> dir);

introduces a ray starting in *p* with direction *dir*.

Precondition: *p* and *dir* have the same dimension and *dir* is not degenerate.

Precondition: *p.dimension()==dir.dimension()*.

Ray_d<Kernel> r(Segment_d<Kernel> s);

introduces a ray through *s.source()* and *s.target()* and starting at *s.source()*.

Precondition: *s* is not degenerate.

Operations

int *r.dimension()* returns the dimension of the ambient space.

Point_d<Kernel> *r.source()* returns the source point of *r*.

<i>Point_d<Kernel></i>	<i>r.point(int i)</i>	returns a point on <i>r</i> . <i>point(0)</i> is the source. <i>point(i)</i> , with $i > 0$, is different from the source. <i>Precondition: $i \geq 0$.</i>
<i>Direction_d<Kernel></i>	<i>r.direction()</i>	returns the direction of <i>r</i> .
<i>Line_d<Kernel></i>	<i>r.supporting_line()</i>	returns the supporting line of <i>r</i> .
<i>Ray_d<Kernel></i>	<i>r.opposite()</i>	returns the ray with direction opposite to <i>r</i> and starting in <i>source</i> .
<i>Ray_d<Kernel></i>	<i>r.transform(Aff_transformation_d<Kernel> t)</i>	returns $t(r)$. <i>Precondition: $r.dimension()=t.dimension()$.</i>
<i>Ray_d<Kernel></i>	<i>r + Vector_d<Kernel> v</i>	returns $r+v$, i.e., <i>r</i> translated by vector <i>v</i> . <i>Precondition: $r.dimension()=v.dimension()$.</i>
<i>bool</i>	<i>r.has_on(Point_d<Kernel> p)</i>	A point is on <i>r</i> , iff it is equal to the source of <i>r</i> , or if it is in the interior of <i>r</i> . <i>Precondition: $r.dimension()=p.dimension()$.</i>

Non-Member Functions

<i>bool</i>	<i>parallel(r1, r2)</i>	returns true if the unoriented supporting lines of <i>r1</i> and <i>r2</i> are parallel and false otherwise. <i>Precondition: $r1.dimension()=r2.dimension()$.</i>
-------------	---------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Implementation

Rays are implemented by a pair of points as an item type. All operations like creation, initialization, tests, direction calculation, input and output on a ray *r* take time $O(r.dimension())$. *dimension()*, coordinate and point access, and identity test take constant time. The space requirement is $O(r.dimension())$.

CGAL::Segment_d<Kernel>

Definition

An instance s of the data type *Segment_d* is a directed straight line segment in d -dimensional Euclidean space connecting two points p and q . p is called the source point and q is called the target point of s , both points are called endpoints of s . A segment whose endpoints are equal is called *degenerate*.

Types

Segment_d<Kernel>::R the representation type.

$$Segment_d<Kernel>:: RT \quad \text{the ring type.}$$

$Segment_d<Kernel>:: FT$ the field type.

Segment_d<Kernel>::LA the linear algebra layer.

Creation

Segment_d<Kernel> *s*;

introduces a variable *s* of type *Segment_d<Kernel>*.

Segment_d<Kernel> *s* (*Point_d<Kernel>* *p*, *Point_d<Kernel>* *q*);

introduces a variable *s* of type *Segment_d<Kernel>* which is initialized to the segment (*p*,*q*).

Precondition: *p.dimension()==q.dimension()*.

Segment_d<Kernel> *s* (*Point_d<Kernel>* *p*, *Vector_d<Kernel>* *v*);

introduces a variable *s* of type *Segment_d<Kernel>* which is initialized to the segment (*p*,*p*+*v*).

Precondition: *p.dimension()*==*v.dimension()*.

Operations

<i>int</i>	<i>s.dimension()</i>	returns the dimension of the ambient space.
------------	----------------------	---------------------------------------------

<i>Point_d<Kernel></i>	<i>s.source()</i>	returns the source point of segment <i>s</i> .
------------------------------	-------------------	------------------------------------------------

<i>Point_d</i> < <i>Kernel</i> >	<i>s.target()</i>	returns the target point of segment <i>s</i> .
----------------------------------	-------------------	------------------------------------------------

<i>Point_d<Kernel></i>	<i>s.vertex(int i)</i>	returns source or target of <i>s</i> : <i>vertex(0)</i> returns the source, <i>vertex(1)</i> returns the target. The parameter <i>i</i> is taken modulo 2, which gives easy access to the other vertex. <i>Precondition: $i \geq 0$.</i>
<i>Point_d<Kernel></i>	<i>s.point(int i)</i>	returns <i>vertex(i)</i> .
<i>Point_d<Kernel></i>	<i>s[int i]</i>	returns <i>vertex(i)</i> .
<i>Point_d<Kernel></i>	<i>s.min()</i>	returns the lexicographically smaller vertex.
<i>Point_d<Kernel></i>	<i>s.max()</i>	returns the lexicographically larger vertex.
<i>Segment_d<Kernel></i>	<i>s.opposite()</i>	returns the segment (<i>target()</i> , <i>source()</i>).
<i>Direction_d<Kernel></i>	<i>s.direction()</i>	returns the direction from source to target. <i>Precondition: s is non-degenerate.</i>
<i>Vector_d<Kernel></i>	<i>s.vector()</i>	returns the vector from source to target.
<i>FT</i>	<i>s.squared_length()</i>	returns the square of the length of <i>s</i> .
<i>bool</i>	<i>s.has_on(Point_d<Kernel> p)</i>	returns true if <i>p</i> lies on <i>s</i> and false otherwise. <i>Precondition: $s.dimension()=p.dimension()$.</i>
<i>Line_d<Kernel></i>	<i>s.supporting_line()</i>	returns the supporting line of <i>s</i> . <i>Precondition: s is non-degenerate.</i>
<i>Segment_d<Kernel></i>	<i>s.transform(Aff_transformation_d<Kernel> t)</i>	returns <i>t(s)</i> . <i>Precondition: $s.dimension()=t.dimension()$.</i>
<i>Segment_d<Kernel></i>	<i>s + Vector_d<Kernel> v</i>	returns <i>s + v</i> , i.e., <i>s</i> translated by vector <i>v</i> . <i>Precondition: $s.dimension()=v.dimension()$.</i>
<i>bool</i>	<i>s.is_degenerate()</i>	returns true if <i>s</i> is degenerate i.e. <i>s.source()=s.target()</i> .

Non-Member Functions

<i>bool</i>	<i>weak_equality(s1, s2)</i>	Test for equality as unoriented segments. <i>Precondition: $s1.dimension()=s2.dimension()$.</i>
-------------	-------------------------------	---------------------------------------------------------------------------------------------------------------

<i>bool</i>	<i>parallel(s1, s2)</i>	return true if one of the segments is degenerate or if the un-oriented supporting lines are parallel. <i>Precondition: s1.dimension()==s2.dimension().</i>
<i>bool</i>	<i>common_endpoint(s1, s2, Point_d<Kernel>& common)</i>	if <i>s1</i> and <i>s2</i> touch in a common end point, this point is assigned to <i>common</i> and the result is <i>true</i> , otherwise the result is <i>false</i> . If <i>s1==s2</i> then one of the endpoints is returned. <i>Precondition: s1.dimension()==s2.dimension().</i>

Implementation

Segments are implemented by a pair of points as an item type. All operations like creation, initialization, tests, the calculation of the direction and source - target vector, input and output on a segment *s* take time $O(s.dimension())$. *dimension()*, coordinate and end point access, and identity test take constant time. The operations for intersection calculation also take time $O(s.dimension())$. The space requirement is $O(s.dimension())$.

CGAL::Hyperplane_d<Kernel>

Definition

An instance of data type *Hyperplane_d* is an oriented hyperplane in d - dimensional space. A hyperplane h is represented by coefficients (c_0, c_1, \dots, c_d) of type *RT*. At least one of c_0 to c_{d-1} must be non-zero. The plane equation is $\sum_{0 \leq i < d} c_i x_i + c_d = 0$, where x_0 to x_{d-1} are Cartesian point coordinates. For a particular x the sign of $\sum_{0 \leq i < d} c_i x_i + c_d$ determines the position of a point x with respect to the hyperplane (on the hyperplane, on the negative side, or on the positive side).

There are two equality predicates for hyperplanes. The (weak) equality predicate (*weak_equality*) declares two hyperplanes equal if they consist of the same set of points, the strong equality predicate (*operator==*) requires in addition that the negative halfspaces agree. In other words, two hyperplanes are strongly equal if their coefficient vectors are positive multiples of each other and they are (weakly) equal if their coefficient vectors are multiples of each other.

Types

Hyperplane_d<Kernel>:: RT

the ring type.

Hyperplane_d<Kernel>:: FT

the field type.

Hyperplane_d<Kernel>:: LA

the linear algebra layer.

Hyperplane_d<Kernel>:: Coefficient_const_iterator

a read-only iterator for the coefficients.

Creation

Hyperplane_d<Kernel> h; introduces a variable h of type *Hyperplane_d<Kernel>*.

template <class InputIterator>

Hyperplane_d<Kernel> h(int d, InputIterator first, InputIterator last, RT D);

introduces a variable h of type *Hyperplane_d<Kernel>* initialized to the hyperplane with coefficients set $[first, last)$ and D .

Precondition: $size [first, last) == d$.

Requirement: The value type of *InputIterator* is *RT*.

template <class InputIterator>

Hyperplane_d<Kernel> h(int d, InputIterator first, InputIterator last);

introduces a variable *h* of type *Hyperplane_d<Kernel>* initialized to the hyperplane with coefficients set *[first,last)*.

Precondition: size *[first,last) == d+1*.

Requirement: The value type of *InputIterator* is *RT*.

template <class ForwardIterator>

*Hyperplane_d<Kernel> h(ForwardIterator first,
ForwardIterator last,
Point_d<Kernel> o,
Oriented_side side = Oriented_side(0))*

constructs some hyperplane that passes through the points in set *[first,last)*. If *side* is *ON_POSITIVE_SIDE* or *ON_NEGATIVE_SIDE* then *o* is on that side of the constructed hyperplane.

Precondition: A hyperplane with the stated properties must exist.

Requirement: The value type of *ForwardIterator* is *Point_d<Kernel>*.

Hyperplane_d<Kernel> h(Point_d<Kernel> p, Direction_d<Kernel> dir);

constructs the hyperplane with normal direction *dir* that passes through *p*. The direction *dir* points into the positive side.

Precondition: *p.dimension() == dir.dimension()* and *dir* is not degenerate.

Hyperplane_d<Kernel> h(RT a, RT b, RT c);

introduces a variable *h* of type *Hyperplane_d<Kernel>* in 2-dimensional space with equation $ax + by + c = 0$.

Hyperplane_d<Kernel> h(RT a, RT b, RT c, RT d);

introduces a variable *h* of type *Hyperplane_d<Kernel>* in 3-dimensional space with equation $ax + by + cz + d = 0$.

Operations

int *h.dimension()* returns the dimension of *h*.

RT *h[int i]* returns the *i*-th coefficient of *h*.
Precondition: $0 \leq i \leq d$.

RT *h.coefficient(int i)*

returns the *i*-th coefficient of *h*.
Precondition: $0 \leq i \leq d$.

<i>Coefficient_const_iterator</i>	<i>h.coefficients_begin()</i>	returns an iterator pointing to the first coefficient.
<i>Coefficient_const_iterator</i>	<i>h.coefficients_end()</i>	returns an iterator pointing beyond the last coefficient.
<i>Vector_d<Kernel></i>	<i>h.orthogonal_vector()</i>	returns the orthogonal vector of <i>h</i> . It points from the negative halfspace into the positive halfspace and its homogeneous coordinates are $(c_0, \dots, c_{d-1}, 1)$.
<i>Direction_d<Kernel></i>	<i>h.orthogonal_direction()</i>	returns the orthogonal direction of <i>h</i> . It points from the negative halfspace into the positive halfspace.
<i>Oriented_side</i>	<i>h.oriented_side(Point_d<Kernel> p)</i>	returns the side of the hyperplane <i>h</i> containing <i>p</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on(Point_d<Kernel> p)</i>	returns true iff point <i>p</i> lies on the hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on_boundary(Point_d<Kernel> p)</i>	returns true iff point <i>p</i> lies on the boundary of hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on_positive_side(Point_d<Kernel> p)</i>	returns true iff point <i>p</i> lies on the positive side of hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on_negative_side(Point_d<Kernel> p)</i>	returns true iff point <i>p</i> lies on the negative side of hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .

Hyperplane_d<Kernel> *h.transform(Aff_transformation_d<Kernel> t)*

returns $t(h)$.

Precondition: $h.dimension() == t.dimension()$.

Non-Member Functions

bool *weak_equality(h1, h2)*

test for weak equality.

Precondition: $h1.dimension() == h2.dimension()$.

Implementation

Hyperplanes are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, vector arithmetic, input and output on a hyperplane h take time $O(h.dimension())$. coordinate access and $dimension()$ take constant time. The space requirement is $O(h.dimension())$.

CGAL::Sphere_d<Kernel>

Definition

An instance S of the data type $Sphere_d$ is an oriented sphere in some d -dimensional space. A sphere is defined by $d + 1$ points (class $Point_d<Kernel>$). We use A to denote the array of the defining points. A set A of defining points is *legal* if either the points are affinely independent or if the points are all equal. Only a legal set of points defines a sphere in the geometric sense and hence many operations on spheres require the set of defining points to be legal. The orientation of S is equal to the orientation of the defining points, i.e., $orientation(A)$.

Types

$Sphere_d<Kernel>:: R$	the representation type.
$Sphere_d<Kernel>:: RT$	the ring type.
$Sphere_d<Kernel>:: FT$	the field type.
$Sphere_d<Kernel>:: LA$	the linear algebra layer.
$Sphere_d<Kernel>:: point_iterator$	a read-only iterator for points defining the sphere.

Creation

$Sphere_d<Kernel> S;$ introduces a variable S of type $Sphere_d<Kernel>$.

`template <class ForwardIterator>`

$Sphere_d<Kernel> S(int d, ForwardIterator first, ForwardIterator last);$

introduces a variable S of type $Sphere_d<Kernel>$. S is initialized to the sphere through the points in $A = tuple [first, last)$.

Precondition: A consists of $d + 1$ d -dimensional points.

Requirement: The value type of `ForwardIterator` is $Point_d<Kernel>$.

Operations

int $S.dimension()$ returns the dimension of the ambient space.

$Point_d<Kernel> S.point(int i)$ returns the i th defining point.
Precondition: $0 \leq i \leq dim$.

<i>point_iterator</i>	<i>S.points_begin()</i>	returns an iterator pointing to the first defining point.
<i>point_iterator</i>	<i>S.points_end()</i>	returns an iterator pointing beyond the last defining point.
<i>bool</i>	<i>S.is_degenerate()</i>	returns true iff the defining points are not full dimensional.
<i>bool</i>	<i>S.is_legal()</i>	returns true iff the set of defining points is legal. A set of defining points is legal iff their orientation is non-zero or if they are all equal.
<i>Point_d<Kernel></i>	<i>S.center()</i>	returns the center of <i>S</i> . <i>Precondition: S is legal.</i>
<i>FT</i>	<i>S.squared_radius()</i>	returns the squared radius of the sphere. <i>Precondition: S is legal.</i>
<i>Orientation</i>	<i>S.orientation()</i>	returns the orientation of <i>S</i> .
<i>Oriented_side</i>	<i>S.oriented_side(Point_d<Kernel> p)</i>	returns either the constant <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_POSITIVE_SIDE</i> , or <i>ON_NEGATIVE_SIDE</i> , iff <i>p</i> lies on the boundary, properly on the positive side, or properly on the negative side of sphere, resp. <i>Precondition: S.dimension()==p.dimension().</i>
<i>Bounded_side</i>	<i>S.bounded_side(Point_d<Kernel> p)</i>	returns <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> , or <i>ON_UNBOUNDED_SIDE</i> iff <i>p</i> lies properly inside, on the boundary, or properly outside of sphere, resp. <i>Precondition: S.dimension()==p.dimension().</i>
<i>bool</i>	<i>S.has_on_positive_side(Point_d<Kernel> p)</i>	returns <i>S.oriented_side(p)==ON_POSITIVE_SIDE</i> . <i>Precondition: S.dimension()==p.dimension().</i>

S.has_on_negative_side(Point_d<Kernel> p)

returns $S.oriented_side(p) == ON_NEGATIVE_SIDE$.

Precondition: $S.dimension()=p.dimension()$.

$$S.has_on_boundary(Point_d<Kernel> p)$$

returns $S.oriented_side(p) == ON_ORIENTED_BOUNDARY$, which is the same as $S.bounded_side(p) == ON_BOUNDARY$.

Precondition: $S.dimension()=p.dimension()$.

S.has_on_bounded_side(Point_d<Kernel> p)

returns $S.bounded_side(p) == ON_BOUNDED_SIDE$.

Precondition: $S.dimension()=p.dimension()$.

$$S.has_on_unbounded_side(Point_d<Kernel> p)$$

returns $S.bounded_side(p) == ON_UNBOUNDED_SIDE$.

Precondition: $S.dimension()=p.dimension()$.

Sphere_d<Kernel>

S.opposite()

returns the sphere with the same center and squared radius as S but with opposite orientation.

Sphere_d<Kernel>

$$S + Vector_d \langle Kernel \rangle v$$

returns the sphere translated by v .

Precondition: $S.dimension() == v.dimension()$.

Non-Member Functions

```
bool      weak_equality( S1, S2)
```

Test for equality as unoriented spheres.

Precondition: $S1.dimension()=S2.dimension()$.

Implementation

Spheres are implemented by a vector of points as a handle type. All operations like creation, initialization, tests, input and output of a sphere s take time $O(s.dimension())$. $dimension()$, point access take constant time. The $center()$ -operation takes time $O(d^3)$ on its first call and constant time thereafter. The sidedness and orientation tests take time $O(d^3)$. The space requirement for spheres is $O(s.dimension())$ neglecting the storage room of the points.

CGAL::Iso_box_d<Kernel>

Definition

An object b of the data type $Iso_box_d<Kernel>$ is an iso-box in the Euclidean space \mathbb{E}^d with edges parallel to the axes of the coordinate system.

Creation

$Iso_box_d<Kernel> \ b(\text{const } Point_d<Kernel>\& \ p, \text{const } Point_d<Kernel>\& \ q);$

introduces an iso-oriented iso-box b with diagonal opposite vertices p and q .

Operations

$bool \qquad b.operator==(\text{const } Iso_box_d<Kernel>\& \ b2) \text{ const}$

Test for equality: two iso-oriented cuboid are equal, iff their lower left and their upper right vertices are equal.

$bool \qquad b.operator!=(\text{const } Iso_box_d<Kernel>\& \ b2) \text{ const}$

Test for inequality.

$\text{const } Point_d<Kernel>\& \quad b.min() \text{ const}$ returns the smallest vertex of b .

$\text{const } Point_d<Kernel>\& \quad b.max() \text{ const}$ returns the largest vertex of b .

Predicates

$bool \qquad b.is_degenerate() \text{ const}$

b is degenerate, if all vertices are collinear.

$Bounded_side \quad b.bounded_side(\text{const } Point_d<Kernel>\& \ p) \text{ const}$

returns either $ON_UNBOUNDED_SIDE$, $ON_BOUNDED_SIDE$, or the constant $ON_BOUNDARY$, depending on where point p is.

$bool \quad b.has_on_boundary(\text{const } Point_d<Kernel>\& \ p) \text{ const}$

$bool \quad b.has_on_bounded_side(\text{const } Point_d<Kernel>\& \ p) \text{ const}$

$bool \quad b.has_on_unbounded_side(\text{const } Point_d<Kernel>\& \ p) \text{ const}$

Miscellaneous

Kernel::FT

b.volume() const

returns the volume of *b*.

CGAL::Aff_transformation_d<Kernel>

Definition

An instance of the data type *Aff_transformation_d<Kernel>* is an affine transformation of d -dimensional space. It is specified by a square matrix M of dimension $d + 1$. All entries in the last row of M except the diagonal entry must be zero; the diagonal entry must be non-zero. A point p with homogeneous coordinates $(p[0], \dots, p[d])$ can be transformed into the point $p.transform(A) = Mp$, where A is an affine transformation created from M by the constructors below.

Types

Aff_transformation_d<Kernel>:: RT

the ring type.

Aff_transformation_d<Kernel>:: FT

the field type.

Aff_transformation_d<Kernel>:: LA

the linear algebra layer.

Aff_transformation_d<Kernel>:: Matrix

the matrix type.

Creation

Aff_transformation_d<Kernel> t;

introduces some transformation.

Aff_transformation_d<Kernel> t(int d, Identity_transformation);

introduces the identity transformation in d -dimensional space.

Aff_transformation_d<Kernel> t(Matrix M);

introduces the transformation of d -space specified by matrix M .

Precondition: M is a square matrix of dimension $d + 1$ where entries in the last row of M except the diagonal entry must be zero; the diagonal entry must be non-zero.

template <typename Forward_iterator>

Aff_transformation_d<Kernel> t(Scaling, Forward_iterator start, Forward_iterator end);

introduces the transformation of d -space specified by a diagonal matrix with entries *set* $[start, end)$ on the diagonal (a scaling of the space).

Precondition: *set* $[start, end)$ is a vector of dimension $d + 1$.

Aff_transformation_d<Kernel> t(Translation, Vector_d<Kernel> v);

introduces the translation by vector v .

Aff_transformation_d<Kernel> t(int d, Scaling, RT num, RT den);

returns a scaling by a scale factor num/den .

Precondition: $den \neq 0$.

Aff_transformation_d<Kernel> t(int d, Rotation, RT sin_num, RT cos_num, RT den, int e1 = 0, int e2 = 1);

returns a planar rotation with sine and cosine values sin_num/den and cos_num/den in the plane spanned by the base vectors b_{e1} and b_{e2} in d -space. Thus the default use delivers a planar rotation in the x - y plane.

Precondition: $sin_num^2 + cos_num^2 = den^2$ and $0 \leq e_1 < e_2 < d$.

Precondition: $den \neq 0$

*Aff_transformation_d<Kernel> t(int d,
Rotation,
Direction_d<Kernel> dir,
RT num,
RT den,
int e1 = 0,
int e2 = 1)*

returns a planar rotation within a two-dimensional linear subspace. The subspace is spanned by the base vectors b_{e1} and b_{e2} in d -space. The rotation parameters are given by the 2-dimensional direction *dir*, such that the difference between the sines and cosines of the rotation given by *dir* and the approximated rotation are at most num/den each.

Precondition: $dir.dimension()=2$, $!dir.is_degenerate()$ and $num < den$ is positive, $den \neq 0$, $0 \leq e_1 < e_2 < d$.

Operations

<i>int</i>	<i>t.dimension()</i>	the dimension of the underlying space
<i>Matrix</i>	<i>t.matrix()</i>	returns the transformation matrix
<i>Aff_transformation_d<Kernel></i>	<i>t.inverse()</i>	returns the inverse transformation. <i>Precondition:</i> <i>t.matrix()</i> is invertible.

Aff_transformation_d<Kernel>

$t * s$

composition of transformations. Note that transformations are not necessarily commutative. $t*s$ is the transformation which transforms first by t and then by s .

Implementation

Affine Transformations are implemented by matrices of number type RT as a handle type. All operations like creation, initialization, input and output on a transformation t take time $O(t.dimension()^2)$. $dimension()$ takes constant time. The operations for inversion and composition have the cubic costs of the used matrix operations. The space requirement is $O(t.dimension()^2)$.

3.7 Global Kernel Functions

CGAL::affinely_independent

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool          affinely_independent( ForwardIterator first, ForwardIterator last)
```

returns true iff the points in $A = \text{tuple } [first, last)$ are affinely independent.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*

CGAL::affine_rank

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
int affine_rank( ForwardIterator first, ForwardIterator last)
```

computes the affine rank of the points in $A = \text{tuple}[first, last)$.

Precondition: The objects in A are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::center_of_sphere

```
#include <CGAL/constructions_d.h>
```

```
template <class ForwardIterator>
```

```
Point_d<R> center_of_sphere( ForwardIterator first, ForwardIterator last)
```

returns the center of the sphere spanned by the points in $A = \text{tuple}[first, last)$.

Precondition: A contains $d + 1$ affinely independent points of dimension d .

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::compare_lexicographically

```
#include <CGAL/predicates_d.h>
```

```
Comparison_result    compare_lexicographically( Point_d<R> p, Point_d<R> q)
```

Compares the Cartesian coordinates of points p and q lexicographically in ascending order of its Cartesian components $p[i]$ and $q[i]$ for $i = 0, \dots, d - 1$.

Precondition: $p.dimension() == q.dimension()$

CGAL::contained_in_affine_hull

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool contained_in_affine_hull( ForwardIterator first,  
                              ForwardIterator last,  
                              Point_d<R> p)
```

determines whether p is contained in the affine hull of the points in $A = \text{tuple } [first, last)$.

Precondition: The objects in A are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::contained_in_linear_hull

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool contained_in_linear_hull( ForwardIterator first,  
                              ForwardIterator last,  
                              Vector_d<R> v)
```

determines whether v is contained in the linear hull of the vectors in $A = \text{tuple } [first, last)$.

Precondition: The objects in A are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Vector_d<R>*.

CGAL::contained_in_simplex

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool contained_in_simplex( ForwardIterator first, ForwardIterator last, Point_d<R> p)
```

determines whether p is contained in the simplex of the points in $A = \text{tuple } [first, last)$.

Precondition: The objects in A are of the same dimension and affinely independent.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::do_intersect

```
#include <CGAL/intersections_d.h>
```

```
bool do_intersect( Type1<R> obj1, Type2<R> obj2)
```

checks whether *obj1* and *obj2* intersect. Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*.

Precondition: the objects are of the same dimension.

The types *Type1* and *Type2* can be any of the following:

- *Point_d<R>*
- *Line_d<R>*
- *Ray_d<R>*
- *Segment_d<R>*
- *Hyperplane_d<R>*

See Also

intersection

CGAL::intersection

```
#include <CGAL/intersections_d.h>
```

Object *intersection*(*Type1*<*R*> *f1*, *Type2*<*R*> *f2*)

returns the intersection result of *f1* and *f2* by means of the polymorphic wrapper type *Object*. The returned object can be tested for the intersection result and assigned by means of the operation *bool assign*(*T*& *t*, *Object* *o*).

Precondition: The objects are of the same dimension.

The possible value for types *Type1* and *Type2* and the possible return values wrapped in *Object* are the following:

Type1	Type2	Return Type
<i>Line_d</i>	<i>Line_d</i>	<i>Point_d</i> , <i>Line_d</i>
<i>Segment_d</i>	<i>Line_d</i>	<i>Point_d</i> , <i>Segment_d</i>
<i>Segment_d</i>	<i>Segment_d</i>	<i>Point_d</i> , <i>Segment_d</i>
<i>Ray_d</i>	<i>Line_d</i>	<i>Point_d</i> , <i>Ray_d</i>
<i>Ray_d</i>	<i>Segment_d</i>	<i>Point_d</i> , <i>Segment_d</i>
<i>Ray_d</i>	<i>Ray_d</i>	<i>Point_d</i> , <i>Segment_d</i> , <i>Ray_d</i>
<i>Hyperplane_d</i>	<i>Line_d</i>	<i>Point_3</i> , <i>Line_3</i>
<i>Hyperplane_d</i>	<i>Ray_d</i>	<i>Point_d</i> , <i>Ray_d</i>
<i>Hyperplane_d</i>	<i>Segment_d</i>	<i>Point_d</i> , <i>Segment_d</i>

Example

The following example demonstrates the most common use of *intersection* routines.

```
#include <CGAL/intersections_d.h>

template <class R>
void foo(Segment_d<R> seg, Line_d<R> lin)
{
    Point_d<R> ipnt; Segment_d<R> iseg;
    Object result = intersection(seg, lin);
    if ( assign(ipnt, result) ) {
        // handle the point intersection case.
    } else if ( assign(iseg, result) ) {
        // handle the segment intersection case.
    } else {
        // handle the no intersection case.
    }
}
```

See Also

do_intersect, *Kernel::Intersect_d*

CGAL::lexicographically_smaller

```
#include <CGAL/predicates_d.h>
```

```
bool                                lexicographically_smaller( Point_d<R> p, Point_d<R> q)
```

returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points.

Precondition: *p.dimension()* == *q.dimension()*.

CGAL::lexicographically_smaller_or_equal

```
#include <CGAL/predicates_d.h>
```

```
bool lexicographically_smaller_or_equal( Point_d<R> p, Point_d<R> q)
```

returns *true* iff p is lexicographically smaller than q with respect to Cartesian lexicographic order of points or equal to q .

Precondition: $p.\text{dimension}() == q.\text{dimension}()$.

CGAL::lift_to_paraboloid

```
#include <CGAL/constructions_d.h>
```

```
Point_d<R> lift_to_paraboloid( Point_d<R> p)
```

returns the projection of $p = (x_0, \dots, x_{d-1})$ onto the paraboloid of revolution which is the point $(p_0, \dots, p_{d-1}, \sum_{0 \leq i < d} p_i^2)$ in $(d+1)$ -space.

CGAL::linearly_independent

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool linearly_independent( ForwardIterator first, ForwardIterator last)
```

decides whether the vectors in $A = \text{tuple } [first, last)$ are linearly independent.

Precondition: The objects in A are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Vector_d<R>*.

CGAL::linear_base

```
#include <CGAL/constructions_d.h>
```

```
template <class ForwardIterator, class OutputIterator>
```

```
OutputIterator linear_base( ForwardIterator first, ForwardIterator last, OutputIterator result)
```

computes a basis of the linear space spanned by the vectors in $A = \text{tuple } [first, last)$ and returns it via an iterator range starting in *result*. The returned iterator marks the end of the output.

Precondition: A contains vectors of the same dimension d .

Requirement: The value type of *ForwardIterator* and *OutputIterator* is $\text{Vector}_d<R>$.

CGAL::linear_rank

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
int linear_rank( ForwardIterator first, ForwardIterator last)
```

computes the linear rank of the vectors in $A = \text{tuple}[first, last)$.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Vector_d<R>*.

CGAL::midpoint

```
#include <CGAL/constructions_d.h>
```

```
Point_d<R> midpoint( Point_d<R> p, Point_d<R> q)
```

computes the midpoint of the segment pq .

Precondition:

Precondition: $p.dimension() == q.dimension()$.

CGAL::orientation

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
Orientation orientation( ForwardIterator first, ForwardIterator last)
```

determines the orientation of the points of the tuple $A = \text{tuple } [first, last)$ where A consists of $d + 1$ points in d -space. This is the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ A[0] & A[1] & \dots & A[d] \end{vmatrix}$$

where $A[i]$ denotes the Cartesian coordinate vector of the i -th point in A .

Precondition: $\text{size } [first, last) == d + 1$ and $A[i].\text{dimension}() == d \forall 0 \leq i \leq d$.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::project_along_d_axis

```
#include <CGAL/constructions_d.h>
```

```
Point_d<R> project_along_d_axis( Point_d<R> p)
```

returns p projected along the d -axis onto the hyperspace spanned by the first $d - 1$ standard base vectors.

CGAL::side_of_bounded_sphere

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
Bounded_side      side_of_bounded_sphere( ForwardIterator first,  
                                           ForwardIterator last,  
                                           Point_d<R> p)
```

returns the relative position of point p to the sphere defined by $A = \text{tuple } [first, last)$. The order of the points of A does not matter.

Precondition: $\text{orientation}(first, last)$ is not *ZERO*.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::side_of_oriented_sphere

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
Oriented_side      side_of_oriented_sphere( ForwardIterator first,
                                             ForwardIterator last,
                                             Point_d<R> p)
```

returns the relative position of point p to the oriented sphere defined by the points in $A = \text{tuple } [first, last)$. The order of the points in A is important, since it determines the orientation of the implicitly constructed sphere. If the points in A are positively oriented, the positive side is the bounded interior of the sphere.

Precondition: A contains $d + 1$ points in d -space.

Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::squared_distance

```
#include <CGAL/constructions_d.h>
```

```
FT squared_distance( Point_d<R> p, Point_d<R> q)
```

computes the square of the Euclidean distance between the two points p and q .

Precondition: The dimensions of p and q are the same.

3.8 Kernel Concept

Kernel_d

The concept of a *kernel* is defined by a set of requirements on the provision of certain types and access member functions to create objects of these types. The types are function object classes to be used within the algorithms and data structures in the basic library of CGAL. This allows you to use any model of a kernel as a traits class in the CGAL algorithms and data structures, unless they require types beyond those provided by a kernel.

Kernel_d subsumes the concept of a *d-dimensional kernel*.

A kernel provides types, construction objects, and generalized predicates. The former replace constructors of the kernel classes and constructive procedures in the kernel. There are also function objects replacing operators, especially for equality testing.

Types

<i>Kernel_d:: FT</i>	a number type that is a model for <i>FieldNumberType</i>
<i>Kernel_d:: RT</i>	a number type that is a model for <i>RingNumberType</i>

Coordinate Access

<i>Kernel_d:: Cartesian_const_iterator_d</i>	a type that allows to iterate over the Cartesian coordinates
----------------------------------------------	--------------------------------------------------------------

Geometric Objects

Kernel_d:: Point_d
Kernel_d:: Vector_d
Kernel_d:: Direction_d
Kernel_d:: Hyperplane_d
Kernel_d:: Line_d
Kernel_d:: Ray_d
Kernel_d:: Segment_d
Kernel_d:: Iso_box_d
Kernel_d:: Sphere_d
Kernel_d:: Aff_transformation_d

Constructions

Kernel_d:: Construct_point_d
Kernel_d:: Construct_vector_d
Kernel_d:: Construct_direction_d
Kernel_d:: Construct_hyperplane_d
Kernel_d:: Construct_segment_d
Kernel_d:: Construct_iso_box_d
Kernel_d:: Construct_line_d

Kernel_d:: Construct_ray_d
Kernel_d:: Construct_sphere_d
Kernel_d:: Construct_aff_transformation_d
Kernel_d:: Construct_cartesian_const_iterator_d

Generalized Predicates

Kernel_d:: Affine_rank_d
Kernel_d:: Affinely_independent_d
Kernel_d:: Barycentric_coordinates_d
Kernel_d:: Center_of_sphere_d
Kernel_d:: Compare_lexicographically_d
Kernel_d:: Component_accessor_d
Kernel_d:: Contained_in_affine_hull_d
Kernel_d:: Contained_in_linear_hull_d
Kernel_d:: Contained_in_simplex_d
Kernel_d:: Equal_d
Kernel_d:: Has_on_positive_side_d
Kernel_d:: Intersect_d
Kernel_d:: Less_lexicographically_d
Kernel_d:: Less_or_equal_lexicographically_d
Kernel_d:: Lift_to_paraboloid_d
Kernel_d:: Linear_base_d
Kernel_d:: Linear_rank_d
Kernel_d:: Linearly_independent_d
Kernel_d:: Midpoint_d
Kernel_d:: Orientation_d
Kernel_d:: Oriented_side_d
Kernel_d:: Orthogonal_vector_d
Kernel_d:: Point_of_sphere_d
Kernel_d:: Point_to_vector_d
Kernel_d:: Position_on_line_d
Kernel_d:: Project_along_d_axis_d
Kernel_d:: Side_of_bounded_sphere_d
Kernel_d:: Side_of_oriented_sphere_d
Kernel_d:: Squared_distance_d
Kernel_d:: Value_at_d
Kernel_d:: Vector_to_point_d

Operations

The following member functions return function objects of the types listed above. The name of the access function is the name of the type returned with an *_object* suffix and no capital letter at the beginning. We only give two examples to show the scheme. For the functors *Construct_point_d* and *Orientation_d* the corresponding functions are:

Kernel::Construct_point_d *kernel.construct_point_d_object()*
Kernel::Orientation_d *kernel.orientation_d_object()*

Has Models

Cartesian_d<FieldNumberType>, Homogeneous_d<RingNumberType>

Kernel::Affinely_independent_d

A model for this must provide:

```
template <class ForwardIterator>
bool fo( ForwardIterator first, ForwardIterator last)
```

returns true iff the points in $A = \text{tuple } [first, last)$ are affinely independent.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Affine_rank_d

A model for this must provide:

```
template <class ForwardIterator>
int fo( ForwardIterator first, ForwardIterator last)
```

computes the affine rank of the points in $A = \text{tuple}[first, last)$.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::CartesianConstIterator_d

A type representing an iterator to the Cartesian coordinates of a point in d dimensions.

Refines

CopyConstructible, Assignable, DefaultConstructible

Is Model for the Concepts

BidirectionalIterator

See Also

Kernel::ConstructCartesianConstIterator_d page [507](#)

Kernel::Center_of_sphere_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Kernel::Point_d fo( ForwardIterator first, ForwardIterator last)
```

computes the affine rank of the points in $A = \text{tuple}[first, last)$.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Compare_lexicographically_d

A model for this must provide:

Comparison_result *fo*(*Kernel::Point_d* *p*, *Kernel::Point_d* *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in ascending order of its Cartesian components *p*[*i*] and *q*[*i*] for *i* = 0, ..., *d* − 1.

Precondition: The objects are of the same dimension.

Kernel::Component_accessor_d

A model for this must provide:

<i>int</i>	<i>fo.dimension(Kernel::Point_d p)</i>	returns the dimension of <i>p</i> .
<i>Kernel::RT</i>	<i>fo.homogeneous(Kernel::Point_d p, int i)</i>	returns the <i>i</i> th homogeneous coordinate of <i>p</i> . <i>Precondition: $0 \leq i \leq \text{dimension}(p)$.</i>
<i>Kernel::FT</i>	<i>fo.cartesian(Kernel::Point_d p, int i)</i>	returns the <i>i</i> th Cartesian coordinate of <i>p</i> . <i>Precondition: $0 \leq i < \text{dimension}(p)$.</i>

Kernel::ConstructCartesianConstIterator_d

A model for this must provide:

Kernel::Cartesian_const_iterator_d

fo(Kernel::Point_d p)

returns an iterator on the 0'th Cartesian coordinate of *p*.

Kernel::Cartesian_const_iterator_d

fo(Kernel::Point_d p, int)

returns the past the end iterator of the Cartesian coordinates of *p*.

Refines

AdaptableFunctor (with one argument)

See Also

Kernel::CartesianConstIterator_d page [503](#)

Kernel::Contained_in_affine_hull_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

determines whether p is contained in the affine hull of the points in $A = \text{tuple } [first, last)$.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Contained_in_linear_hull_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Vector_d v)
```

determines whether v is contained in the linear hull of the vectors in $A = \text{tuple } [first, last)$.

Precondition: The objects are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Kernel::Vector_d*.

Kernel::Contained_in_simplex_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

determines whether p is contained in the simplex of the points in $A = \text{tuple } [first, last)$.

Precondition: The objects in A are of the same dimension and affinely independent.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Equal_d

A model for this must provide:

bool

fo(Kernel::Point_d p, Kernel::Point_d q)

returns true iff p and q are equal (as d -dimensional points).

Precondition: p and q have the same dimension.

Kernel::Has_on_positive_side_d

A model for this must provide:

```
template <class Kernel_object>
bool fo( Kernel_object o, Kernel::Point_d p)
```

returns true iff p is on the positive side of o .
 $Kernel_object$ may be any of $Kernel::Sphere_d$,
 $Kernel::Hyperplane_d$.
Precondition: p and o have the same dimension.

Kernel::Intersect_d

A model for this must provide:

```
template <class Kernel_object>
Object      fo( Kernel_object p, Kernel_object q)
```

returns the result of the intersection of p and q in form of a polymorphic object. *Kernel_object* may be any of *Kernel::Segment_d*, *Kernel::Ray_d*, *Kernel::Line_d*, *Kernel::Hyperplane_d*.

Precondition: p and q have the same dimension.

Kernel::Less_lexicographically_d

A model for this must provide:

bool *fo(Kernel::Point_d p, Kernel::Point_d q)*

returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points.
Precondition: *p* and *q* have the same dimension.

Kernel::Less_or_equal_lexicographically_d

A model for this must provide:

bool *fo*(*Kernel::Point_d* *p*, *Kernel::Point_d* *q*)

returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points or equal to *q*.

Precondition: *p* and *q* have the same dimension.

Kernel::Lift_to_paraboloid_d

A model for this must provide:

Kernel::Point_d \rightarrow *fo(Kernel::Point_d p)*

returns $p = (x_0, \dots, x_{d-1})$ lifted to the paraboloid of revolution which is the point $(p_0, \dots, p_{d-1}, \sum_{0 \leq i < d} p_i^2)$ in $(d+1)$ -space.

Kernel::Linearly_independent_d

A model for this must provide:

```
template <class ForwardIterator>
bool fo( ForwardIterator first, ForwardIterator last)
```

decides whether the vectors in $A = \text{tuple } [first, last)$ are linearly independent.

Precondition: The objects in A are of the same dimension.

Requirement: The value type of *ForwardIterator* is *Kernel_d::Vector_d*.

Kernel::Linear_base_d

A model for this must provide:

```
template <class ForwardIterator, class OutputIterator>
int fo( ForwardIterator first, ForwardIterator last, OutputIterator result)
```

computes a basis of the linear space spanned by the vectors in $A = \text{tuple } [first, last)$ and returns it via an iterator range starting in *result*. The returned iterator marks the end of the output.

Precondition: A contains vectors of the same dimension d .

Requirement: The value type of *ForwardIterator* and *OutputIterator* is *Kernel::Vector_d*.

Kernel::Linear_rank_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
int fo( ForwardIterator first, ForwardIterator last)
```

computes the linear rank of the vectors in $A = \text{tuple}[first, last)$.

Precondition:

Precondition: A contains vectors of the same dimension d .

Requirement: The value type of *ForwardIterator* is *Kernel::Vector_d*.

Kernel::Midpoint_d

A model for this must provide:

Kernel::Point_d *fo(Kernel::Point_d p, Kernel::Point_d q)*

computes the midpoint of the segment pq .

Precondition: p and q have the same dimension.

Kernel::Orientation_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Orientation fo( ForwardIterator first, ForwardIterator last)
```

determines the orientation of the points of the tuple $A = \text{tuple } [first, last)$ where A consists of $d + 1$ points in d -space. This is the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ A[0] & A[1] & \dots & A[d] \end{vmatrix}$$

where $A[i]$ denotes the cartesian coordinate vector of the i -th point in A .

Precondition: $\text{size } [first, last) == d + 1$ and $A[i].\text{dimension}() == d \forall 0 \leq i \leq d$.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Oriented_side_d

A model for this must provide:

```
template <class Kernel_object>
Oriented_side fo( Kernel_object o, Kernel::Point_d p)
```

returns the side of p with respect to o . *Kernel_object* may be any of *Kernel::Sphere_d* or *Kernel::Hyperplane_d*.
Precondition: p and o have the same dimension.

Kernel::Orthogonal_vector_d

A model for this must provide:

Kernel::Vector_d *fo(Kernel::Hyperplane_d h)*
 computes an orthogonal vector to *h*.

Kernel::Point_of_sphere_d

A model for this must provide:

```
bool fo( Kernel::Sphere_d s, int i)
    returns the ith point defining the sphere s.
```

Kernel::Point_to_vector_d

A model for this must provide:

Kernel::Vector_d *fo(Kernel::Point_d p)*

converts p to its geometric vector.

Kernel::Project_along_d_axis_d

A model for this must provide:

Kernel::Point_d \rightarrow *fo(Kernel::Point_d p)*

returns p projected along the d -axis onto the hyperspace spanned by the first $d - 1$ standard base vectors.

Kernel::Side_of_bounded_sphere_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

returns the relative position of point p to the sphere defined by $A = \text{tuple } [first, last]$. The order of the points of A does not matter.

Precondition: $\text{orientation}(first, last)$ is not ZERO.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Side_of_oriented_sphere_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

returns the relative position of point p to the oriented sphere defined by the points in $A = \text{tuple } [first, last)$. The order of the points in A is important, since it determines the orientation of the implicitly constructed sphere. If the points in A are positively oriented, the positive side is the bounded interior of the sphere.

Precondition: A contains $d + 1$ points in d -space.

Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Squared_distance_d

A model for this must provide:

Kernel::FT *fo(Kernel::Point_d p, Kernel::Point_d q)*

computes the square of the Euclidean distance between the two points p and q .

Precondition: The dimensions of p and q are the same.

Kernel::Value_at_d

A model for this must provide:

Kernel::FT $fo(\textit{Kernel::Hyperplane_d } h, \textit{Kernel::Point_d } p)$

computes the value of h evaluated at p .

Precondition: p and h have the same dimension.

Kernel::Vector_to_point_d

A model for this must provide:

Kernel::Point_d *fo(Kernel::Vector_d v)*

converts v to the affine point $0 + v$.

4.1 Introduction

The goal of the circular kernel is to offer to the user a large set of functionalities on circles and circular arcs in the plane. All the choices (interface, robustness, representation, and so on) made here are consistent with the choices made in the CGAL kernel, for which we refer the user to the 2D kernel manual.

In this first release, all functionalities necessary for computing an arrangement of circular arcs and these line segments are defined. Three traits classes are provided for the CGAL arrangement package.

4.2 Software Design

The design is done in such a way that the algebraic concepts and the geometric concepts are clearly separated. *Circular_kernel_2* has therefore two template parameters:

- the *LinearKernel*, from which the circular kernel derives, provides all elementary geometric objects like points, lines, circles, and elementary functionality on them. It must be a model of the CGAL two dimensional *Kernel* concept.
- the second parameter is the algebraic kernel, which is responsible for computations on polynomials and algebraic numbers. It has to be a model of concept *AlgebraicKernelForCircles*. The robustness of the package relies on the fact that the algebraic kernel provides exact computations on algebraic objects.

The circular kernel uses the extensibility scheme presented in the 2D kernel manual (see Section 2.5). The types of *LinearKernel* are inherited by the circular kernel and some types are taken from the *AlgebraicKernelForCircles* parameter. Three new main geometric objects are introduced by *Circular_kernel_2*: circular arcs, points of circular arcs (used in particular for endpoints of arcs and intersection points between arcs) and line segments whose endpoints are points of this new type.

In fact, the circular kernel is documented as a concept, *CircularKernel*, and two models are provided:

- *Circular_kernel_2<LinearKernel,AlgebraicKernelForCircles>*, the basic kernel,
- and a predefined filtered kernel *Exact_circular_kernel_2*, that is based on similar techniques as *Exact_predicates_exact_constructions_kernel*.

More work is in progress to increase the efficiency of this filtered kernel and provide other filtering techniques.

4.3 Examples

4.3.1 Computing an Arrangement of Random Circles

This example shows how to construct incrementally an arrangement of circles, using the traits class for arrangement of circular arcs provided with the package.

```
#include <CGAL/basic.h>
#include <CGAL/Cartesian.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_2.h>

#include <CGAL/MP_Float.h>

#include <CGAL/Algebraic_kernel_2_2.h>

#include <CGAL/Circular_kernel.h>

#include <CGAL/Arr_circular_arc_traits.h>

#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

typedef CGAL::Quotient<CGAL::MP_Float> NT;
typedef CGAL::Cartesian<NT> Linear_k;

typedef CGAL::Algebraic_kernel_for_circles_2_2<NT> Algebraic_k;
typedef CGAL::Circular_kernel_2<Linear_k,Algebraic_k> Circular_k;

typedef Circular_k::Point_2 Point_2;
typedef Circular_k::Circle_2 Circle_2;
typedef Circular_k::Circular_arc_2 Circular_arc_2;
typedef std::vector<Circular_arc_2> ArcContainer;
```

```

typedef CGAL::Arr_circular_arc_traits<Circular_k> Traits;

typedef CGAL::Arrangement_2<Traits> Arr;
typedef CGAL::Arr_naive_point_location<Arr> Point_location;

int main(){

    CGAL::Random generatorOfgenerator;
    int random_seed = generatorOfgenerator.get_int(0, 123456);
    std::cout << "random_seed = " << random_seed << std::endl;
    CGAL::Random theRandom(random_seed);
    int random_max = 128;
    int random_min = -128;
    ArcContainer ac;
    int x, y;

    for (int i = 0; i < 10; i++) {
        x = theRandom.get_int(random_min, random_max);
        y = theRandom.get_int(random_min, random_max);
        ac.push_back( Circle_2( Point_2(x,y), x*x + y*y));
    }

    Arr _pm;
    Point_location _pl(_pm);
    for (ArcContainer::const_iterator it=ac.begin(); it != ac.end(); ++it) {
        insert_curve(_pm,*it,_pl);
    };

    return 0;
};

```

4.3.2 Constructing an Arrangement of Circles and Segments

In this example, the traits class using the `boost::variant` is used in order to provide arrangements with curves that can be either circular arcs or line segments.

```

#include <CGAL/basic.h>
#include <CGAL/Cartesian.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_2.h>

#include <CGAL/MP_Float.h>
#include <CGAL/Gmpq.h>

#include <CGAL/Algebraic_kernel_2_2.h>

#include <CGAL/Circular_kernel.h>

#include <CGAL/Arr_circular_line_arc_traits.h>

```

```

#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

typedef CGAL::Gmpq NT;
typedef CGAL::Cartesian<NT> Linear_k;

typedef CGAL::Algebraic_kernel_for_circles_2_2<NT> Algebraic_k;
typedef CGAL::Circular_kernel_2<Linear_k,Algebraic_k> Circular_k;

typedef Circular_k::Point_2 Point_2;
typedef Circular_k::Circle_2 Circle_2;
typedef Circular_k::Circular_arc_2 Circular_arc_2;
typedef Circular_k::Line_arc_2 Line_arc_2;

typedef boost::variant< Circular_arc_2, Line_arc_2> Arc;
typedef std::vector< Arc> ArcContainer;

typedef CGAL::Arr_circular_line_arc_traits
<Circular_k, Circular_arc_2, Line_arc_2> Traits;

typedef CGAL::Arrangement_2<Traits> Arr;
typedef CGAL::Arr_naive_point_location<Arr> Point_location;

int main(){

    CGAL::Random generatorOfgenerator;
    int random_seed = generatorOfgenerator.get_int(0, 123456);
    std::cout << "random_seed = " << random_seed << std::endl;
    CGAL::Random theRandom(random_seed);
    int random_max = 128;
    int random_min = -128;
    ArcContainer ac;
    int x1, y1, x2, y2;

    for (int i = 0; i < 10; i++) {
        x1 = theRandom.get_int(random_min,random_max);
        y1 = theRandom.get_int(random_min,random_max);
        do{
            x2 = theRandom.get_int(random_min,random_max);
            y2 = theRandom.get_int(random_min,random_max);
        } while((x1 == x2) && (y1 == y2));
        std::cout << x1 << " " << y1 << " " << x2 << " " << y2 << std::endl;

        boost::variant< Circular_arc_2, Line_arc_2 >
            v = Line_arc_2(Point_2(x1,y1), Point_2(x2,y2));
        ac.push_back( v);
    }

    for (int i = 0; i < 10; i++) {
        x1 = theRandom.get_int(random_min,random_max);
        y1 = theRandom.get_int(random_min,random_max);

        boost::variant< Circular_arc_2, Line_arc_2 >

```

```

        v = Circle_2( Point_2(x1,y1), x1*x1 + y1*y1);
        ac.push_back(v);
    }

    Arr _pm;
    Point_location _pl(_pm);
    for (ArcContainer::const_iterator it=ac.begin(); it != ac.end(); ++it) {
        insert_curve(_pm,*it,_pl);
    };

    return 0;
};

```

4.3.3 Using the Predefined Kernel

```

#include <CGAL/basic.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_2.h>

#include <CGAL/Exact_circular_kernel.h>

#include <CGAL/Arr_circular_line_arc_traits.h>

#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

typedef CGAL::Exact_circular_kernel_2          Circular_k;

typedef Circular_k::Point_2                    Point_2;
typedef Circular_k::Circle_2                   Circle_2;
typedef Circular_k::Circular_arc_2             Circular_arc_2;
typedef Circular_k::Line_arc_2                 Line_arc_2;

typedef boost::variant< Circular_arc_2, Line_arc_2> Arc;
typedef std::vector< Arc> ArcContainer;

typedef CGAL::Arr_circular_line_arc_traits
    <Circular_k, Circular_arc_2, Line_arc_2> Traits;

typedef CGAL::Arrangement_2<Traits>            Arr;
typedef CGAL::Arr_naive_point_location<Arr>    Point_location;

int main(){

    CGAL::Random generatorOfgenerator;
    int random_seed = generatorOfgenerator.get_int(0, 123456);
    std::cout << "random_seed = " << random_seed << std::endl;
    CGAL::Random theRandom(random_seed);
    int random_max = 128;
    int random_min = -128;

```

```

ArcContainer ac;
int x1, y1, x2, y2;

for (int i = 0; i < 10; i++) {
    x1 = theRandom.get_int(random_min,random_max);
    y1 = theRandom.get_int(random_min,random_max);
    do{
        x2 = theRandom.get_int(random_min,random_max);
        y2 = theRandom.get_int(random_min,random_max);
    } while((x1 == x2) && (y1 == y2));
    std::cout << x1 << " " << y1 << " " << x2 << " " << y2 << std::endl;

    boost::variant< Circular_arc_2, Line_arc_2 >
        v = Line_arc_2(Point_2(x1,y1), Point_2(x2,y2));
    ac.push_back( v);
}

for (int i = 0; i < 10; i++) {
    x1 = theRandom.get_int(random_min,random_max);
    y1 = theRandom.get_int(random_min,random_max);

    boost::variant< Circular_arc_2, Line_arc_2 >
        v = Circle_2( Point_2(x1,y1), x1*x1 + y1*y1);
    ac.push_back(v);
}

Arr_pm;
Point_location _pl(_pm);
for (ArcContainer::const_iterator it=ac.begin(); it != ac.end(); ++it) {
    insert_curve(_pm,*it,_pl);
};

return 0;
};

```

4.4 Design and Implementation History

The first pieces of prototype code were comparisons of algebraic numbers of degree 2, written by Olivier Devillers [DFMT00, DFMT02], and that are still used in the current implementation of *CGAL::Root_of_2*.

Some work was then done in the direction of a “kernel” for CGAL.¹ and the first design emerged in [EKP⁺04].

The code of this package was written by Sylvain Pion and Monique Teillaud who also wrote the manual. Athanasios Kakargias worked on an prototype version of this kernel in 2003. Julien Hazebrouck participated in the implementation of this kernel in July and August 2005.

Some work is in progress on the implementation of a 3D kernel for circles, circular arcs and spherical patches (with the participation of Julien Hazebrouck and Damien Leroy).

--------------------------------------	-----------------------------------------------

Operations

As in the *Kernel* concept, for each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *CircularKernel::Construct_circular_arc_2* the following member function must exist:

Construct_circular_arc_2

ck.construct_circular_arc_2_object()

CGAL::Circular_kernel_2<LinearKernel,AlgebraicKernelForCircles>

`#include <CGAL/Circular_kernel.h>`

Is Model for the Concepts

CircularKernel

Parameters

The circular kernel is parameterized by a *LinearKernel* parameter (and derives from it), in order to reuse all needed functionalities on basic linear objects provided by one of the CGAL kernels. It also allows other implementations of these basic functionalities.

The second parameter, *AlgebraicKernelForCircles*, is meant to provide the circular kernel with all the algebraic functionalities required for the manipulation of algebraic curves.

Inherits From

LinearKernel

Types

The circular kernel uses basic number types of the algebraic kernel:
`typedef AlgebraicKernelForCircles::RT` *RT*; Ring number type.

`typedef AlgebraicKernelForCircles::FT` *FT*; Field number type.

In fact, the two number types *AlgebraicKernelForCircles::RT* and *LinearKernel::RT* must coincide, as well as *AlgebraicKernelForCircles::FT* and *LinearKernel::FT*.

The following types are available, as well as all the functionality on them described in the *CircularKernel* concept.

```
typedef Line_arc_2<Circular_kernel_2>      Line_arc_2;
typedef Circular_arc_2<Circular_kernel_2>   Circular_arc_2;
typedef Circular_arc_point_2<Circular_kernel_2>
                                           Circular_arc_point_2;
```

Constructs an arc from a full circle.

```
Circular_arc_2<CircularKernel> ca( CircularKernel::Circle_2 c,
    CircularKernel::Circular_arc_point_2 p1,
    CircularKernel::Circular_arc_point_2 p2)
```

Constructs the circular arc supported by *c*, that is oriented counterclockwise, whose source is *p1* and whose target is *p2*.

Precondition: *p1* and *p2* lie on *c*.

Access Functions

```
CircularKernel::Circle_2 ca.supporting_circle()
```

A circular arc is supposed to be oriented counterclockwise, from *source* to *target*.

```
CircularKernel::Circular_arc_point_2 ca.source()
CircularKernel::Circular_arc_point_2 ca.target()
```

When the methods *source* and *target* return the same point, then the arc is in fact a full circle.

When an arc is x-monotone, its left and right points can be accessed directly:

```
CircularKernel::Circular_arc_point_2 ca.left()           Precondition: ca.is_x_monotone().
CircularKernel::Circular_arc_point_2 ca.right()          Precondition: ca.is_x_monotone().
```

Query Functions

```
bool ca.is_x_monotone() Tests whether the arc is x-monotone.
bool ca.is_y_monotone() Tests whether the arc is y-monotone.
```

I/O

istream& *std::istream*& *is* >> *Circular_arc_2* & *ca*
ostream& *std::ostream*& *os* << *Circular_arc_2* *ca*

Circular_arc_point_2<CircularKernel> p( CircularKernel::Point_2 q);
```

```
Circular_arc_point_2<CircularKernel> p( CircularKernel::Root_for_circles_2_2 r);
```

Access Functions

<i>CircularKernel::Root_of_2</i>	<i>p.x()</i>	<i>x</i> -coordinate of the point.
<i>CircularKernel::Root_of_2</i>	<i>p.y()</i>	<i>y</i> -coordinate of the point.

<i>Bbox_2</i>	<i>p.bbox()</i>	Returns a bounding box around the point.
---------------	-----------------	------------------------------------------

Operations

<i>bool</i>	<i>p == q</i>	Test for equality. Two points are equal, iff their <i>x</i> and <i>y</i> coordinates are equal.
-------------	---------------	-------------------------------------------------------------------------------------------------

<i>bool</i>	<i>p != q</i>	Test for nonequality.
-------------	---------------	-----------------------

<i>bool</i>	<i>p < q</i>	Returns true iff <i>p</i> is lexicographically smaller than <i>q</i> , i.e. either if <i>p.x()</i> < <i>q.x()</i> or if <i>p.x()</i> == <i>q.x()</i> and <i>p.y()</i> < <i>q.y()</i> .
-------------	-----------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>bool</i>	<i>p > q</i>	Returns true iff <i>p</i> is lexicographically greater than <i>q</i> .

CircularKernel::ConstructLine_2

Refines

Kernel::ConstructLine_2

A model *fo* of this type must provide:

CircularKernel::Line_2 *fo*(*CircularKernel::Polynomial_1_2*)

Constructs a line from an equation.

See Also

CircularKernel::GetEquation page [585](#)

CircularKernel::ConstructCircle_2

Refines

Kernel::ConstructCircle_2

A model *fo* of this type must provide:

CircularKernel::Circle_2

fo(CircularKernel::Polynomial_for_circles_2_2)

Constructs a circle from an equation.

See Also

CircularKernel::GetEquation page [585](#)

CircularKernel::ConstructCircularArcPoint_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Root_for_circles_2_2 r)

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Point_2 p)

CircularKernel::ConstructLineArc_2

A model *fo* of this type must provide:

CircularKernel::Line_arc_2

```
fo.operator()( CircularKernel::Line_2 l,
                CircularKernel::Circular_arc_point_2 p1,
                CircularKernel::Circular_arc_point_2 p2)
```

Constructs the line segment supported by *l*, whose source is *p1* and whose target is *p2*.

Precondition: *p1* and *p2* lie on *l*.

CircularKernel::Line_arc_2

```
fo( CircularKernel::Segment_2 s)
```

CircularKernel::Line_arc_2

```
fo( CircularKernel::Point_2 p1, CircularKernel::Point_2 p2)
```

CircularKernel::Line_arc_2

```
fo.operator()( CircularKernel::Line_2 l,
                CircularKernel::Circle_2 c1,
                bool b1,
                CircularKernel::Circle_2 c2,
                bool b2)
```

Constructs the line segment whose supporting line is *l*, whose source endpoint is the b_1^h intersection of *l* with *c1*, and whose target endpoint is the b_2^h intersection of *l* and *c2*, where intersections are ordered lexicographically.

Precondition: *l* intersects both *c1* and *c2*, and the arc defined by the intersections has non-zero length.

CircularKernel::Line_arc_2

```
fo.operator()( CircularKernel::Line_2 l,
                CircularKernel::Line_2 l1,
                CircularKernel::Line_2 l2)
```

Same, for intersections defined by lines instead of circles.

CircularKernel::ConstructCircularArc_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_2

fo(*CircularKernel::Circle_2* *c*)

Constructs an arc from a full circle.

CircularKernel::Circular_arc_2

fo.operator()(*CircularKernel::Circle_2* *c*,
CircularKernel::Circular_arc_point_2 *p1*,
CircularKernel::Circular_arc_point_2 *p2*)

Construct the circular arc supported by *c*, that is oriented counterclockwise, whose source is *p1* and whose target is *p2*.

Precondition: *p1* and *p2* lie on *c*.

CircularKernel::Circular_arc_2

fo.operator()(*CircularKernel::Circle_2* *c*,
CircularKernel::Circle_2 *c1*,
bool *b1*,
CircularKernel::Circle_2 *c2*,
bool *b2*)

Constructs the unique circular arc that is oriented counterclockwise, whose supporting circle is *c*, and whose source endpoint is the intersection of *c* and *c1* with index *b1*, and whose target is the intersection of *c* and *c2* of index *b2*, where intersections are ordered lexicographically.

Precondition: *c* intersects both *c1* and *c2*, and the arc defined by the intersections has non-zero length.

CircularKernel::Circular_arc_2

fo.operator()(*CircularKernel::Circle_2* *c*,
CircularKernel::Line_2 *l1*,
bool *b1*,
CircularKernel::Line_2 *l2*,
bool *b2*)

Same, for intersections defined by lines instead of circles.

CircularKernel::ConstructCircularMinVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the *x*-minimal vertex of *c*.
Precondition: The arc *c* is *x*-monotone.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

CircularKernel::ConstructCircularMaxVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the *x*-maximal vertex of *c*.

Precondition: The arc *c* is *x*-monotone.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

CircularKernel::ConstructCircularSourceVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the source vertex of *c*.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

CircularKernel::ConstructCircularTargetVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the target vertex of *c*.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

CircularKernel::ConstructBbox_2

A model *fo* of this type must provide operators to construct a bounding box of geometric objects:

CGAL::Bbox_2 *fo*(*CircularKernel::Circular_arc_point_2* *p*)

CGAL::Bbox_2 *fo*(*CircularKernel::Line_arc_2* *l*)

CGAL::Bbox_2 *fo*(*CircularKernel::Circular_arc_2* *c*)

CircularKernel::CompareX_2

Refines

Kernel::CompareX_2

An object *fo* of this type must provide in addition:

```
Comparison_result      fo.operator()( CircularKernel::Circular_arc_point_2 p,
                    CircularKernel::Circular_arc_point_2 q)
```

Compares the x -coordinates of p and q .

See Also

<i>CircularKernel::CompareY_2</i>	page 571
<i>CircularKernel::CompareXY_2</i>	page 572
<i>CircularKernel::Equal_2</i>	page 578

Refines

An object *fo* of this type must provide in addition:

Compares the y -coordinates of p and q .

<i>CircularKernel::CompareX_2</i>	page 570
<i>CircularKernel::CompareXY_2</i>	page 572
<i>CircularKernel::Equal_2</i>	page 578

CircularKernel::CompareXY_2

Refines

Kernel::CompareXY_2

An object *fo* of this type must provide in addition:

[illegible]

Compares p and q according to the lexicographic ordering on x - and y -coordinates.

See Also

<i>CircularKernel::CompareX_2</i>	page 570
<i>CircularKernel::CompareY_2</i>	page 571
<i>CircularKernel::Equal_2</i>	page 578

CircularKernel::CompareYatX_2

An object *fo* of this type must provide two operators that compare a point *p* and an arc *a* on the vertical line passing through *p*.

Comparison_result *fo*(*CircularKernel::Circular_arc_point_2* *p*, *CircularKernel::Circular_arc_2* *a*)

For a circular arc.

Precondition: The arc *a* must be monotone and *p* must be in the vertical range of *a*.

Comparison_result *fo*(*CircularKernel::Circular_arc_point_2* *p*, *CircularKernel::Line_arc_2* *a*)

Same for a segment.

CircularKernel::MakeXMonotone_2

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator fo( CircularKernel::Circular_arc_2 ca, OutputIterator oit)
```

Splits the arc *ca* into monotone arcs that are returned through the output iterator.

For the sake of completeness, the *operator()* must also be defined for a *Line_arc_2*. In this case, the input line arc itself is the only arc returned through the *OutputIterator*.

CircularKernel::Intersect_2

Refines

Kernel::Intersect_2

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator fo( Type1 obj1, Type2 obj2, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*.

where *Type_1* and *Type_2* can both be either

- *CircularKernel::Line_arc_2* or
- *CircularKernel::Circle_2* or
- *CircularKernel::Circular_arc_2*.

Depending on the types *Type_1* and *Type_2*, these elements can be assigned to

- *std::pair<CircularKernel::Circular_arc_point_2, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj_1* and *obj_2* or
- *CircularKernel::Circular_arc_2* in case of an overlap.

CircularKernel::Split_2

A model *fo* of this type must provide:

```
void fo.operator()( CircularKernel::Circular_arc_2 a,
                    CircularKernel::Circular_arc_point_2 p,
                    CircularKernel::Circular_arc_2 &a1,
                    CircularKernel::Circular_arc_2 &a2)
```

Splits arc *a* at point *p*, which creates arcs *a1* and *a2*.
Precondition: *a* is *x*-monotone, and *p* lies on *a*.

```
void fo.operator()( CircularKernel::Line_arc_2 l,
                    CircularKernel::Circular_arc_point_2 p,
                    CircularKernel::Line_arc_2 &l1,
                    CircularKernel::Line_arc_2 &l2)
```

Same for a line arc.

CircularKernel::Equal_2

Definition

Testing equality between objects.

Refines

Kernel::Equal_2

An object *fo* of this type must provide in addition:

bool *fo.operator()*(*CircularKernel::Circular_arc_point_2* p0,
CircularKernel::Circular_arc_point_2 p1)

For two points.

bool *fo*(*CircularKernel::Circular_arc_2* a0, *CircularKernel::Circular_arc_2* a1)

For two arcs.

bool *fo*(*CircularKernel::Line_arc_2* a0, *CircularKernel::Line_arc_2* a1)

For two segments.

For the sake of completeness, the *operator()* must also be defined for a *Line_arc_2* and a *Circular_arc_2* as arguments (in any order), and it always returns *false*.

See Also

CircularKernel::HasOn_2

Definition

To test whether a point lies on a curve.

An object *fo* of this type must provide:

bool *fo*(*CircularKernel::Line_2* l, *CircularKernel::Circular_arc_point_2* p)

For a line.

bool *fo*(*CircularKernel::Circle_2* c, *CircularKernel::Circular_arc_point_2* p)

For a circle.

bool *fo*(*CircularKernel::Line_arc_2* l, *CircularKernel::Circular_arc_point_2* p)

For a line arc.

bool *fo*(*CircularKernel::Circular_arc_2* c, *CircularKernel::Circular_arc_point_2* p)

For a circular arc.

Precondition: c is x-monotone.

CircularKernel::DoOverlap_2

Definition

Testing whether the interiors of two curves overlap.

An object *fo* of this type must provide:

bool *fo*(*CircularKernel::Line_arc_2* l0, *CircularKernel::Line_arc_2* l1)

For two line arcs.

bool *fo*(*CircularKernel::Circular_arc_2* a0, *CircularKernel::Circular_arc_2* a1)

For two circular arcs.

Precondition: a_0 and a_1 are *x*-monotone.

CircularKernel::InXRange_2

Definition

To test whether a point lies in the vertical range of a curve.

An object *fo* of this type must provide:

bool *fo*(CircularKernel::Line_arc_2 l, CircularKernel::Circular_arc_point_2 p)

For a line arc.

bool *fo*(CircularKernel::Circular_arc_2 c, CircularKernel::Circular_arc_point_2 p)

For a circular arc.

Precondition: *c* is *x*-monotone.

CircularKernel::IsVertical_2

Refines

Kernel::IsVertical_2

An object *fo* of this type must provide:

bool *fo(CircularKernel::Line_arc_2 l)*
For a line arc.

bool *fo(CircularKernel::Circular_arc_2 c)*
For a circular arc, always returns *false*.

CircularKernel::IsXMonotone_2

An object *fo* of this type must provide:

<i>bool</i>	<i>fo</i> (CircularKernel::Circular_arc_2 <i>c</i>)	Tests whether the arc is <i>x</i> -monotone.
<i>bool</i>	<i>fo</i> (CircularKernel::Line_arc_2 <i>l</i>)	For a line arc, always returns <i>true</i> .

CircularKernel::IsYMonotone_2

An object *fo* of this type must provide:

<i>bool</i>	<i>fo</i> (<i>CircularKernel::Circular_arc_2</i> <i>c</i>)	Tests whether the arc is y-monotone.
<i>bool</i>	<i>fo</i> (<i>CircularKernel::Line_arc_2</i> <i>l</i>)	For a line arc, always returns <i>true</i> .

CircularKernel::GetEquation

A model *fo* of this type must provide:

CircularKernel::Polynomial_1_2

fo(CircularKernel::Line_2 c)

Returns the equation of the line.

CircularKernel::Polynomial_for_circles_2_2

fo(CircularKernel::Circle_2 c)

Returns the equation of the circle.

AlgebraicKernelForCircles

Definition

The *AlgebraicKernelForCircles* concept is meant to provide the curved kernel with all the algebraic functionalities required for the manipulation of circular arcs.

Has Models

Algebraic_kernel_for_circles_2_2

Types

A model of *AlgebraicKernelForCircles* is supposed to provide

AlgebraicKernelForCircles:: RT
AlgebraicKernelForCircles:: FT

A model of *RingNumberType*.
 A model of *FieldNumberType*<*RT*>.

AlgebraicKernelForCircles:: Polynomial_1_2

A model of *AlgebraicKernelForCircles::Polynomial_1_2*, for bivariate polynomials of degree up to 1.

AlgebraicKernelForCircles:: Polynomial_for_circles_2_2

A model of *AlgebraicKernelForCircles::PolynomialForCircles_2_2*, for bivariate polynomials of degree up to 2 that can store equations of circles.

AlgebraicKernelForCircles:: Root_of_2

A model of *RootOf_2*, for algebraic numbers of degree up to 2.

AlgebraicKernelForCircles:: Root_for_circles_2_2

A model of *AlgebraicKernelForCircles::RootForCircles_2_2*, for solutions of systems of two models of *AlgebraicKernelForCircles::PolynomialForCircles_2_2*.

AlgebraicKernelForCircles:: Construct_polynomial_1_2

A model of *AlgebraicKernelForCircles::ConstructPolynomial_1_2*.

AlgebraicKernelForCircles:: Construct_polynomial_for_circles_2_2

A model of *AlgebraicKernelForCircles::ConstructPolynomialForCircles_2_2*.

AlgebraicKernelForCircles:: Compare_x

A model of the concept *AlgebraicKernelForCircles::CompareX*.

<i>AlgebraicKernelForCircles:: Compare_y</i>	A model of the concept <i>AlgebraicKernelForCircles::CompareY</i> .
<i>AlgebraicKernelForCircles:: Compare_xy</i>	A model of the concept <i>AlgebraicKernelForCircles::CompareXY</i> .
<i>AlgebraicKernelForCircles:: Sign_at</i>	A model of the concept <i>AlgebraicKernelForCircles::SignAt</i> .
<i>AlgebraicKernelForCircles:: X_critical_points</i>	A model of the concept <i>AlgebraicKernelForCircles::XCriticalPoints</i> .
<i>AlgebraicKernelForCircles:: Y_critical_points</i>	A model of the concept <i>AlgebraicKernelForCircles::YCriticalPoints</i> .
<i>AlgebraicKernelForCircles:: Solve</i>	A model of the concept <i>AlgebraicKernelForCircles::Solve</i> .

AlgebraicKernelForCircles::SignAt

Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
CGAL::Sign          fo.operator()( AlgebraicKernelForCircles::Polynomial_1_2 p,
                                   AlgebraicKernelForCircles::Root_for_circles_2_2 r)
```

Computes the sign of polynomial *p* evaluated at a root *r*.

```
template < class OutputIterator >
CGAL::Sign          fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p,
                                   AlgebraicKernelForCircles::Root_for_circles_2_2 r)
```

Same as previous.

AlgebraicKernelForCircles::ConstructPolynomial_1_2

A model *fo* of this type must provide:

AlgebraicKernelForCircles::Polynomial_1_2

```
fo.operator()( AlgebraicKernelForCircles::RT a,
               AlgebraicKernelForCircles::RT b,
               AlgebraicKernelForCircles::RT c)
```

Constructs polynomial $ax+by+c$.

See Also

CircularKernel::ConstructLine_2page [560](#)
CircularKernel::GetEquationpage [585](#)

AlgebraicKernelForCircles::ConstructPolynomialForCircles_2_2

A model *fo* of this type must provide:

AlgebraicKernelForCircles::PolynomialForCircles_2_2

```
fo.operator()( const AlgebraicKernelForCircles::FT a,
               const AlgebraicKernelForCircles::FT b,
               const AlgebraicKernelForCircles::FT rsq)
```

Constructs polynomial $(x-a)^2 + (y-b)^2 - rsq$.

AlgebraicKernelForCircles::Solve

Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_1_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_1_2 p2,
                                   OutputIterator res)
```

Copies in the output iterator the common roots of *p1* and *p2*, with their multiplicity, as objects of type *std::pair< AlgebraicKernelForCircles::Root_for_circles_2_2, int>*.

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_1_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p2,
                                   OutputIterator res)
```

Same as previous.

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_1_2 p2,
                                   OutputIterator res)
```

Same as previous.

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p2,
                                   OutputIterator res)
```

Same as previous.

AlgebraicKernelForCircles::XCriticalPoints

Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p,
                                   OutputIterator res)
```

Copies in the output iterator the *x*-critical points of polynomial *p*, as objects of type *AlgebraicKernelForCircles::Root_for_circles_2_2*.

```
template < class OutputIterator >
AlgebraicKernelForCircles::Root_for_circles_2_2
```

```
fo( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, bool i)
```

Computes the *i*th *x*-critical point of polynomial *p*.

AlgebraicKernelForCircles::YCriticalPoints

Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p,
                                   OutputIterator res)
```

Copies in the output iterator the y-critical points of polynomial *p*, as objects of type *AlgebraicKernelForCircles::Root_for_circles_2_2*.

```
template < class OutputIterator >
AlgebraicKernelForCircles::Root_for_circles_2_2
```

```
fo( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, bool i)
```

Computes the *i*th y-critical point of polynomial *p*.

5.5 Traits Classes	611
5.6 Convexity Checking	612

5.1 Introduction

A subset $S \subseteq \mathbb{R}^2$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S . The convex hull of a set S is the smallest convex set containing S . The convex hull of a set of points P is a convex polygon with vertices in P . A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P . A set of points is said to be strongly convex if it consists of only extreme points.

This chapter describes the functions provided in CGAL for producing convex hulls in two dimensions as well as functions for checking if sets of points are strongly convex or not. There are also a number of functions described for computing particular extreme points and subsequences of hull points, such as the lower and upper hull of a set of points.

5.2 Convex Hull

CGAL provides implementations of several classical algorithms for computing the counterclockwise sequence of extreme points for a set of points in two dimensions (*i.e.*, the counterclockwise sequence of points on the convex hull). The algorithms have different asymptotic running times and require slightly different sets of geometric primitives. Thus you may choose the algorithm that best fits your setting.

Each of the convex hull functions presents the same interface to the user. That is, the user provides a pair of iterators, *first* and *beyond*, an output iterator *result*, and a traits class *traits*. The points in the range $[first, beyond)$ define the input points whose convex hull is to be computed. The counterclockwise sequence of extreme points is written to the sequence starting at position *result*, and the past-the-end iterator for the resulting set of points is returned. The traits classes for the functions specify the types of the input points and the geometric primitives that are required by the algorithms. All functions provide an interface in which this class need not be specified and defaults to types and operations defined in the kernel in which the input point type is defined.

Given a sequence of n input points with h extreme points, the function `convex_hull_2` uses either the output-sensitive $O(nh)$ algorithm of Bykat [Byk78] (a non-recursive version of the quickhull [BDH96] algorithm) or the algorithm of Akl and Toussaint, which requires $O(n \log n)$ time in the worst case. The algorithm chosen depends on the kind of iterator used to specify the input points. These two algorithms are also available via the functions `ch_bykat` and `ch_akl_toussaint`, respectively. Also available are the $O(n \log n)$ Graham-Andrew scan algorithm [And79, Meh84] (`ch_graham_andrew`), the $O(nh)$ Jarvis march algorithm [Jar73] (`ch_jarvis`), and Eddy's $O(nh)$ algorithm [Edd77] (`ch_eddy`), which corresponds to the two-dimensional version of the quickhull algorithm. The linear-time algorithm of Melkman for producing the convex hull of simple polygonal chains (or polygons) is available through the function `ch_melkman`.

5.3 Example using Graham-Andrew's Algorithm

In the following example a convex hull is constructed from point data read from standard input using *Graham-Andrew* algorithm. The resulting convex polygon is shown at the standard output console. The same results could be achieved by substituting the function `CGAL::ch_graham_andrew` by other function like `CGAL::ch_bykat`.

```
// file: examples/Convex_hull_2/ch_example_from_cin_to_cout.C
```

```

#include <CGAL/Cartesian.h>
#include <CGAL/ch_graham_andrew.h>

typedef    CGAL::Point_2<CGAL::Cartesian<double> >    Point_2;

int main()
{
    CGAL::set_ascii_mode(std::cin);
    CGAL::set_ascii_mode(std::cout);
    std::istream_iterator< Point_2 >  in_start( std::cin );
    std::istream_iterator< Point_2 >  in_end;
    std::ostream_iterator< Point_2 >  out( std::cout, "\n" );
    CGAL::ch_graham_andrew( in_start, in_end, out );
    return 0;
}

```

5.4 Extreme Points and Hull Subsequences

In addition to the functions for producing convex hulls, there are a number of functions for computing sets and sequences of points related to the convex hull. The functions *lower_hull_points_2* and *upper_hull_points_2* provide the computation of the counterclockwise sequence of extreme points on the lower hull and upper hull, respectively. The algorithm used in these functions is Andrew's variant of Graham's scan algorithm [And79, Meh84], which has worst-case running time of $O(n \log n)$.

There are also functions available for computing certain subsequences of the sequence of extreme points on the convex hull. The function *ch_jarvis_march* generates the counterclockwise ordered subsequence of extreme points between a given pair of points and *ch_graham_andrew_scan* computes the sorted sequence of extreme points that are not left of the line defined by the first and last input points.

Finally, a set of functions (*ch_nswe_point*, *ch_ns_point*, *ch_we_point*, *ch_n_point*, *ch_s_point*, *ch_w_point*, *ch_e_point*) is provided for computing extreme points of a 2D point set in the coordinate directions.

5.5 Traits Classes

Each of the functions used to compute convex hulls or extreme points is parameterized by a traits class, which specifies the types and geometric primitives to be used in the computation. There are several implementations of 2D traits classes provided in the library. The class *Convex_hull_traits_2<R>* corresponds to the default traits class that provides the types and predicates presented in the 2-dimensional CGAL kernel in which the input points lie. The class *Convex_hull_constructive_traits<R>* is a second traits class based on CGAL primitives but differs from *Convex_hull_traits_2* in that some of its primitives reuse intermediate results to speed up computation. In addition, there are three projective traits classes (*Convex_hull_projective_xy_traits_2*, *Convex_hull_projective_xz_traits_2*, and *Convex_hull_projective_yz_traits_2*), which may be used to compute the convex hull of a set of three-dimensional points projected into each of the three coordinate planes.

5.6 Convexity Checking

The functions *is_ccw_strongly_convex_2* and *is_cw_strongly_convex_2* check whether a given sequence of 2D points forms a (counter)clockwise strongly convex polygon.. These are used in postcondition testing of the two-dimensional convex hull functions.

2D Convex Hulls and Extreme Points

Reference Manual

Susan Hert and Stefan Schirra

A subset $S \subseteq \mathbb{R}^2$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S . The convex hull of a set S is the smallest convex set containing S . The convex hull of a set of points P is a convex polygon with vertices in P . A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P .

CGAL provides functions for computing convex hulls in two dimensions as well as functions for testing if a given set of points is strongly convex or not. There are also a number of functions available for computing particular extreme points in 2D and subsequences of the hull points, such as the lower hull or upper hull of a set of points.

5.7 Classified Reference Pages

Assertions

The assertion flags for the convex hull and extreme point algorithms use *CH* in their names (e.g., *CGAL_CH_NO_POSTCONDITIONS*). For the convex hull algorithms, the postcondition check tests only convexity (if not disabled), but not containment of the input points in the polygon or polyhedron defined by the output points. The latter is considered an expensive checking and can be enabled by defining *CGAL_CH_CHECK_EXPENSIVE*.

CGAL::ch_aki_toussaint

Definition

The function *ch_aki_toussaint* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_aki_toussaint.h>
```

```
template <class ForwardIterator, class OutputIterator, class Traits>
OutputIterator      ch_aki_toussaint( ForwardIterator first,
                                     ForwardIterator beyond,
                                     OutputIterator result,
                                     Traits ch_traits = Default_traits())
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *ForwardIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Less_xy_2*,
 - *Traits::Less_yx_2*,
 - *Traits::Left_turn_2*,
 - *Traits::Equal_2*.

CGAL::convex_hull_2 page 639

Implementation

This function uses the algorithm of Akl and Toussaint [[AT78](#)] that requires $O(n \log n)$ time for n input points.

CGAL::ch_bykat

Definition

The function *ch_bykat* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_bykat.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_bykat( InputIterator first,
                             InputIterator beyond,
                             OutputIterator result,
                             Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Less_signed_distance_to_line_2*,
 - *Traits::Left_turn_2*,
 - *Traits::Less_xy_2*,
 - *Traits::Equal_2*.

Implementation

This function implements the non-recursive variation of Eddy's algorithm [Edd77] described in [Byk78]. This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_eddy

Definition

The function *ch_eddy* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_eddy.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_eddy( InputIterator first,
                             InputIterator beyond,
                             OutputIterator result,
                             Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Equal_2*,
 - *Traits::Less_signed_distance_to_line_2*,
 - *Traits::Left_turn_2*,
 - *Traits::Less_xy_2*.

CGAL::convex_hull_2 page [639](#)

Implementation

This function implements Eddy's algorithm [Edd77], which is the two-dimensional version of the quickhull algorithm [BDH96] . This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_e_point

Definition

The function *ch_e_point* finds a point of a given set of input points with maximal x coordinate.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_e_point( ForwardIterator first,
                     ForwardIterator beyond,
                     ForwardIterator& e,
                     Traits ch_traits = Default_traits)
```

traverses the range $[first, beyond)$. After execution, the value of e is an iterator in the range such that $*e \geq_{xy} *it$ for all iterators it in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines a type *Traits::Less_xy_2* as described in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_graham_andrew

Definition

The function `ch_graham_andrew` generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_graham_andrew.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_graham_andrew( InputIterator first,
                                     InputIterator beyond,
                                     OutputIterator result,
                                     Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range $[first, beyond)$. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

Precondition: The source range $[first, beyond)$ does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Less_xy_2*,
 - *Traits::Left_turn_2*,
 - *Traits::Equal_2*.

<i>CGAL::lower_hull_points_2</i>	page 650
<i>CGAL::upper_hull_points_2</i>	page 652

Implementation

This function implements Andrew’s variant of the Graham scan algorithm [[And79](#)] and follows the presentation of Mehlhorn [[Meh84](#)]. This algorithm requires $O(n \log n)$ time in the worst case for n input points.

CGAL::ch_graham_andrew_scan

Definition

The function `ch_graham_andrew_scan` generates the counterclockwise sequence of extreme points from a given set of input points that are not left of the line defined by the first and last points in this sequence.

```
#include <CGAL/ch_graham_andrew.h>
```

```
template <class BidirectionalIterator, class OutputIterator, class Traits>
OutputIterator      ch_graham_andrew_scan( BidirectionalIterator first,
                                           BidirectionalIterator beyond,
                                           OutputIterator result,
                                           Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points that are not left of pq , where p is the value of *first* and q is the value of *beyond* $- 1$. The resulting sequence is placed starting at *result* with p ; point q is omitted. The past-the-end iterator for the sequence is returned.

Precondition: The range $[first, beyond)$ contains at least two different points. The points in $[first, beyond)$ are “sorted” with respect to pq , i.e., the sequence of points in $[first, beyond)$ define a counterclockwise polygon, for which the Graham-Sklansky-procedure [Sk172] works.

The default traits class *Default_traits* is the kernel in which the type *BidirectionalIterator::value_type* is defined.

Requirements

1. *BidirectionalIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following two types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Left_turn_2*.

Implementation

The function uses Andrew’s variant of the Graham scan algorithm [And79] . This algorithm requires $O(n \log n)$ time in the worst case for n input points.

Example

In the following example *ch_graham_andrew_scan()* is used to realize Anderson's variant [And78] of the Graham Scan [Gra72]. The points are sorted counterclockwise around the leftmost point using the *Less_rotate_ccw_2* predicate, as defined in the concept *ConvexHullTraits_2*. According to the definition of *Less_rotate_ccw_2*, the leftmost point is the last point in the sorted sequence and its predecessor on the convex hull is the first point in the sorted sequence. It is not hard to see that the preconditions of *ch_graham_andrew_scan()* are satisfied. Anderson's variant of the Graham scan is usually inferior to Andrew's variant because of its higher arithmetic demand.

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator
ch_graham_anderson( InputIterator first, InputIterator beyond,
                    OutputIterator result, const Traits& ch_traits)
{
    typedef typename Traits::Less_xy_2          Less_xy_2;
    typedef typename Traits::Point_2           Point_2;
    typedef typename Traits::Less_rotate_ccw_2  Less_rotate_ccw_2;

    if (first == beyond) return result;
    std::vector< Point_2 > V;
    copy( first, beyond, back_inserter(V) );
    typename std::vector< Point_2 >::iterator it =
        std::min_element(V.begin(), V.end(), Less_xy_2());
    std::sort( V.begin(), V.end(), CGAL::bind_1(Less_rotate_ccw_2(), *it) );
    if ( *(V.begin()) == *(V.rbegin()) )
    {
        *result = *(V.begin()); ++result;
        return result;
    }
    return ch_graham_andrew_scan( V.begin(), V.end(), result, ch_traits);
}
```

CGAL::ch_jarvis

Definition

The function *ch_jarvis* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_jarvis.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_jarvis( InputIterator first,
                              InputIterator beyond,
                              OutputIterator result,
                              Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Equal_2*,
 - *Traits::Less_rotate_ccw_2*,
 - *Traits::Less_xy_2*.

Implementation

This function uses the Jarvis march (gift-wrapping) algorithm [Jar73]. This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_jarvis_march

Definition

The function *ch_jarvis_march* generates the counterclockwise sequence of extreme points from a given set of input points that line between two input points.

```
#include <CGAL/ch_jarvis.h>
```

```
template <class ForwardIterator, class OutputIterator, class Traits>
OutputIterator ch_jarvis_march( ForwardIterator first,
                               ForwardIterator beyond,
                               Traits::Point_2 start_p,
                               Traits::Point_2 stop_p,
                               OutputIterator result,
                               Traits ch_traits = Default_traits)
```

generates the counterclockwise subsequence of extreme points between *start_p* and *stop_p* of the points in the range *[first,beyond)*, starting at position *result* with point *start_p*. The last point generated is the point preceding *stop_p* in the counterclockwise order of extreme points.

Precondition: *start_p* and *stop_p* are extreme points with respect to the points in the range *[first,beyond)* and *stop_p* is an element of range *[first,beyond)*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *ForwardIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Equal_2*,
 - *Traits::Less_rotate_ccw_2*.

Implementation

The function uses the Jarvis march (gift-wrapping) algorithm [Jar73]. This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_melkman

Definition

The function *ch_melkman* computes the counterclockwise sequence of extreme points of a sequence of points that forms a simple polyline or polygon.

```
#include <CGAL/ch_melkman.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator      ch_melkman( InputIterator first,
                               InputIterator last,
                               OutputIterator result,
                               Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range $[first, beyond)$. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned.

Precondition: The source range $[first, beyond)$ corresponds to a simple polyline. $[first, beyond)$ does not contain *result*

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Equal_2*,
 - *Traits::Less_xy_2*,
 - *Traits::Left_turn_2*.

Implementation

It uses an implementation of Melkman's algorithm [Mel87]. Running time of this is linear.

CGAL::ch_nswe_point

Definition

The function *ch_nswe_point* finds the four extreme points of a given set of input points using a linear scan of the input points. That is, it determines the points with maximal y, minimal y, minimal x, and maximal x coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void ch_nswe_point( ForwardIterator first,
                   ForwardIterator beyond,
                   ForwardIterator& n,
                   ForwardIterator& s,
                   ForwardIterator& w,
                   ForwardIterator& e,
                   Traits ch_traits = Default_traits)
```

traverses the range $[first, beyond)$. After execution, the value of n is an iterator in the range such that $*n \geq_{yx} *it$ for all iterators it in the range. Similarly, for s , w , and e the inequalities $*s \leq_{yx} *it$, $*w \leq_{xy} *it$, and $*e \geq_{xy} *it$ hold for all iterators it in the range.

Requirements

Traits contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:

- *Traits::Less_xy_2*,
- *Traits::Less_yx_2*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

CGAL::ch_ns_point

Definition

The function *ch_ns_point* finds the points of a given set of input points with minimal and maximal x coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_ns_point( ForwardIterator first,
                      ForwardIterator beyond,
                      ForwardIterator& n,
                      ForwardIterator& s,
                      Traits ch_traits = Default_traits)
```

traverses the range $[first, beyond)$. After execution, the value of n is an iterator in the range such that $*n \geq_{yx} *it$ for all iterators it in the range. Similarly, for s the inequality $*s \leq_{yx} *it$ holds for all iterators in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_yx_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_n_point

Definition

The function *ch_n_point* finds a point in a given set of input points with maximal y coordinate.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_n_point( ForwardIterator first,
                      ForwardIterator beyond,
                      ForwardIterator& n,
                      Traits ch_traits = Default_traits)
```

traverses the range $[first, beyond)$. After execution, the value of *n* is an iterator in the range such that $*n \geq_{yx} *it$ for all iterators *it* in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_yx_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_s_point

Definition

The function *ch_s_point* finds a points in a given set of input points with minimal y coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_s_point( ForwardIterator first,
                     ForwardIterator beyond,
                     ForwardIterator& s,
                     Traits ch_traits = Default_traits)
```

traverses the range *[first,beyond)*. After execution, the value of *s* is an iterator in the range such that $*s \leq_{yx} *it$ for all iterators *it* in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_yx_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_we_point

Definition

The function *ch_we_point* finds two points of a given set of input points with minimal and maximal x coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_we_point( ForwardIterator first,
                      ForwardIterator beyond,
                      ForwardIterator& w,
                      ForwardIterator& e,
                      Traits ch_traits = Default_traits)
```

traverses the range $[first, beyond)$. After execution, the value of w is an iterator in the range such that $*w \leq_{xy} *it$ for all iterators it in the range. Similarly, for e the inequality $*e \geq_{xy} *it$ holds for all iterators in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_xy_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_w_point

Definition

The function *ch_w_point* finds a point in a given set of input points with minimal x coordinate.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void ch_w_point( ForwardIterator first,
                 ForwardIterator beyond,
                 ForwardIterator& w,
                 Traits ch_traits = Default_traits)
```

traverses the range $[first, beyond)$. After execution, the value of w is an iterator in the range such that $*w \leq_{xy} *it$ for all iterators it in the range.

Requirements

Traits defines the type *Traits::Less_xy_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

CGAL::convex_hull_2

Definition

The function *convex_hull_2* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/convex_hull_2.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator          convex_hull_2( InputIterator first,
                                      InputIterator beyond,
                                      OutputIterator result,
                                      Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Equal_2*,
 - *Traits::Less_xy_2*,
 - *Traits::Less_yx_2*,
 - *Traits::Left_turn_2*.

CGAL::ch_graham_andrew page [623](#)
CGAL::ch_jarvis page [627](#)
CGAL::ch_melkman page [631](#)

Implementation

One of two algorithms is used, depending on the type of iterator used to specify the input points. For input iterators, the algorithm used is that of Bykat [Byk78], which has a worst-case running time of $O(nh)$, where n is the number of input points and h is the number of extreme points. For all other types of iterators, the $O(n \log n)$ algorithm of Akl and Toussaint [AT78] is used.

Example

In the following example we use the STL-compliant interface of *CGAL::Polygon_2* to construct the convex hull polygon from the sequence of extreme points. Point data are read from standard input, the convex hull polygon is shown in a CGAL window. Remember, that when no traits class is specified for the function *convex_hull_2*, the kernel from which the input points come is used as the default traits class.

ConvexHullTraits_2

Definition

All convex hull and extreme point algorithms provided in CGAL are parameterized with a traits class *Traits*, which defines the primitives (objects and predicates) that the convex hull algorithms use. ConvexHullTraits_2 defines the complete set of primitives required in these functions. The specific subset of these primitives required by each function is specified with each function.

Types

<i>ConvexHullTraits_2:: Point_2</i>	The point type on which the convex hull functions operate.
<i>ConvexHullTraits_2:: Equal_2</i>	Binary predicate object type comparing <i>Point_2</i> s. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p ==_{xy} q$, false otherwise.
<i>ConvexHullTraits_2:: Less_xy_2</i>	Binary predicate object type comparing <i>Point_2</i> s lexicographically. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote x and y coordinate of point p , respectively.
<i>ConvexHullTraits_2:: Less_yx_2</i>	Same as <i>Less_xy_2</i> with the roles of x and y interchanged.
<i>ConvexHullTraits_2:: Left_turn_2</i>	Predicate object type that must provide <i>bool operator()(Point_2 p, Point_2 q, Point_2 r)</i> , which returns <i>true</i> iff r lies to the left of the oriented line through p and q .
<i>ConvexHullTraits_2:: Less_signed_distance_to_line_2</i>	Predicate object type that must provide <i>bool operator()(Point_2 p, Point_2 q, Point_2 r, Point_2 s)</i> , which returns <i>true</i> iff the signed distance from r to the line l_{pq} through p and q is smaller than the distance from s to l_{pq} . It is used to compute the point right of a line with maximum unsigned distance to the line. The predicate must provide a total order compatible with convexity, <i>i.e.</i> , for any line segment s one of the endpoints of s is the smallest point among the points on s , with respect to the order given by <i>Less_signed_distance_to_line_2</i> .
<i>ConvexHullTraits_2:: Less_rotate_ccw_2</i>	Predicate object type that must provide <i>bool operator()(Point_2 e, Point_2 p, Point_2 q)</i> , where <i>true</i> is returned iff a tangent at e to the point set $\{e, p, q\}$ hits p before q when rotated counterclockwise around e . Ties are broken such that the point with larger distance to e is smaller!

Creation

Only a copy constructor is required.

```
ConvexHullTraits_2 traits( & t);
```

Operations

The following member functions to create instances of the above predicate object types must exist.

```
Equal_2                traits.equal_2_object()  
Less_xy_2             traits.less_xy_2_object()  
Less_yx_2             traits.less_yx_2_object()  
Less_signed_distance_to_line_2  
                        traits.less_signed_distance_to_line_2_object()  
Less_rotate_ccw_2     traits.less_rotate_ccw_2_object()  
Left_turn_2           traits.left_turn_2_object()
```

CGAL::Convex_hull_constructive_traits_2<R>

Definition

The class *Convex_hull_constructive_traits_2<R>* serves as a traits class for all the two-dimensional convex hull and extreme point calculation function. Unlike the class *CGAL::Convex_hull_traits_2<R>*, this class makes use of previously computed results to avoid redundancy. For example, in the sidedness tests, lines (of type *R::Line_2*) are constructed, which is equivalent to the precomputation of subdeterminants of the orientation-determinant for three points.

```
#include <CGAL/convex_hull_constructive_traits_2.h>
```

Is Model for the Concepts

CGAL::is_ccw_strongly_convex_2

Definition

The function *is_ccw_strongly_convex_2* determines if a given sequence of points defines a counterclockwise-oriented, strongly convex polygon. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

```
#include <CGAL/convexity_check_2.h>
```

```
template <class ForwardIterator, class Traits>
```

```
bool is_ccw_strongly_convex_2( ForwardIterator first,
                               ForwardIterator beyond,
                               Traits ch_traits = Default_traits)
```

returns *true*, iff the point elements in $[first, beyond)$ form a counterclockwise-oriented strongly convex polygon.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:

- *Traits::Less_xy_2*,
- *Traits::Equal_2*,
- *Traits::Left_turn_2*.

Implementation

The algorithm requires $O(n)$ time for a set of n input points.

CGAL::lower_hull_points_2

Definition

The function *lower_hull_points_2* generates the counterclockwise sequence of extreme points on the lower hull of a given set of input points.

```
#include <CGAL/convex_hull_2.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator          lower_hull_points_2( InputIterator first,
                                           InputIterator beyond,
                                           OutputIterator result,
                                           Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points on the lower hull of the points in the range *[first, beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. The sequence starts with the leftmost point; the rightmost point is not included. If there is only one extreme point (*i.e.*, leftmost and rightmost point are equal) the extreme point is reported.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

The different treatment by *CGAL::upper_hull_points_2* of the case that all points are equal ensures that concatenation of lower and upper hull points gives the sequence of extreme points.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
 - *Traits::Point_2*,
 - *Traits::Equal_2*,
 - *Traits::Less_xy_2*,
 - *Traits::Less_yx_2*,
 - *Traits::Left_turn_2*.

CGAL::upper_hull_points_2

Definition

The function *upper_hull_points_2* generates the counterclockwise sequence of extreme points on the upper hull of a given set of input points.

```
#include <CGAL/convex_hull_2.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator      upper_hull_points_2( InputIterator first,
                                         InputIterator beyond,
                                         OutputIterator result,
                                         Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points on the upper hull of the points in the range *[first, beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. The sequence starts with the rightmost point, the leftmost point is not included. If there is only one extreme point (*i.e.*, the leftmost and rightmost point are equal), the extreme point is not reported.

Precondition: The source range *[first,beyond)* does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

The different treatment by *CGAL::lower_hull_points_2* of the case that all points are equal ensures that concatenation of lower and upper hull points gives the sequence of extreme points.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:

6.1 Introduction

A subset $S \subseteq \mathbb{R}^3$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S . The convex hull of a set S is the smallest convex set containing S . The convex hull of a set of points $P \in \mathbb{R}^3$ is a convex polytope with vertices in P . A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P . A set of points is said to be strongly convex if it consists of only extreme points.

This chapter describes the functions provided in CGAL for producing convex hulls in three dimensions as well as functions for checking if sets of points are strongly convex are not. One can compute the convex hull of a set of points in three dimensions in one of three ways in CGAL: using a static algorithm, using an incremental construction algorithm, or using a triangulation to get a fully dynamic computation.

6.2 Static Convex Hull Construction

The function `convex_hull_3` provides an implementation of the quickhull algorithm [BDH96] for three dimensions. There are two versions of this function available, one that can be used when it is known that the output will be a polyhedron (*i.e.*, there are more than three points and they are not all collinear) and one that handles all degenerate cases and returns a `CGAL::Object`, which may be a point, a segment, a triangle, or a polyhedron. Both versions accept a range of input iterators defining the set of points whose convex hull is to be computed and a traits class defining the geometric types and predicates used in computing the hull.

6.2.1 Traits Class

The function `convex_hull_3` is parameterized by a traits class, which specifies the types and geometric primitives to be used in the computation. The default for this traits class is `Convex_hull_traits_3`.

6.2.2 Convexity Checking

The function `is_strongly_convex_3` implements the algorithm of Mehlhorn *et al.* [MNS⁺96] to determine if the vertices of a given polytope constitute a strongly convex point set or not. This function is used in postcondition testing for `convex_hull_3`.

6.2.3 Example

The following program computes the convex hull of a set of 250 random points chosen from a sphere of radius 100. It then determines if the resulting hull is a segment or a polyhedron.

```
// file: examples/Convex_hull_3/ch_quickhull_3_ex.C

#include <CGAL/Homogeneous.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/copy_n.h>
#include <CGAL/Convex_hull_traits_3.h>
#include <CGAL/convex_hull_3.h>
#include <vector>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float RT;
#endif

typedef CGAL::Homogeneous<RT> K;
typedef CGAL::Convex_hull_traits_3<K> Traits;
typedef Traits::Polyhedron_3 Polyhedron_3;
typedef K::Segment_3 Segment_3;

// define point creator
typedef K::Point_3 Point_3;
typedef CGAL::Creator_uniform_3<double, Point_3> PointCreator;

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3, PointCreator> gen(100.0);

    // generate 250 points randomly on a sphere of radius 100.0
    // and copy them to a vector
    std::vector<Point_3> points;
```

```

CGAL::copy_n( gen, 250, std::back_inserter(points) );

// define object to hold convex hull
CGAL::Object ch_object;

// compute convex hull
CGAL::convex_hull_3(points.begin(), points.end(), ch_object);

// determine what kind of object it is
Segment_3 segment;
Polyhedron_3 polyhedron;
if ( CGAL::assign(segment, ch_object) )
    std::cout << "convex hull is a segment " << std::endl;
else if ( CGAL::assign (polyhedron, ch_object) )
    std::cout << "convex hull is a polyhedron " << std::endl;
else
    std::cout << "convex hull error!" << std::endl;

return 0;
}

```

6.3 Incremental Convex Hull Construction

The function *convex_hull_incremental_3* provides an interface similar to *convex_hull_3* for the d -dimensional incremental construction algorithm [CMS93], implemented by the class *CGAL::Convex_hull_d<R>* that is specialized to three dimensions. This function accepts an iterator range over a set of input points and returns a polyhedron, but it does not have a traits class in its interface. It uses the kernel class *Kernel* used in the polyhedron type to define an instance of the adapter traits class *CGAL::Convex_hull_d_traits_3<Kernel>*.

In most cases, the function *convex_hull_3* will be faster than *convex_hull_incremental_3*. The latter is provided mainly for comparison purposes.

To use the full functionality available with the d -dimensional class *CGAL::Convex_hull_d<R>* in three dimensions (e.g., the ability to insert new points and to query if a point lies in the convex hull or not), you can instantiate the class *CGAL::Convex_hull_d<K>* with the adapter traits class *CGAL::Convex_hull_d_traits_3<K>*, as shown in the following example.

    return 0;
}

#endif

```

6.4 Dynamic Convex Hull Construction

Fully dynamic maintenance of a convex hull can be achieved by using the class *CGAL::Delaunay_triangulation_3*. This class supports insertion and removal of points (*i.e.*, vertices of the triangulation) and the convex hull edges are simply the finite edges of infinite faces. The following example illustrates the dynamic construction of a convex hull. First, random points from a sphere of a certain radius are generated and are inserted into a triangulation. Then the number of points of the convex hull are obtained by counting the number of triangulation vertices incident to the infinite vertex. Some of the points are removed and then the number of points remaining on the hull are determined. Notice that the vertices incident to the infinite vertex of the triangulation are on the convex hull but it may be that not all of them are vertices of the hull.

6.4.1 Example

```

// file: examples/Convex_hull_3/dynamic_hull_3_ex.C

#include <CGAL/Simple_cartesian.h>

```

```

#include <CGAL/Filtered_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/copy_n.h>

#include <list>

typedef CGAL::Simple_cartesian<double> SK;
typedef CGAL::Filtered_kernel<SK> FK;
struct K : public FK {};

typedef K::Point_3 Point_3;
typedef CGAL::Delaunay_triangulation_3<K> Delaunay;
typedef Delaunay::Vertex_handle Vertex_handle;

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3> gen(100.0);
    std::list<Point_3> points;

    // generate 250 points randomly on a sphere of radius 100.0
    // and insert them into the triangulation
    CGAL::copy_n(gen, 250, std::back_inserter(points) );
    Delaunay T;
    T.insert(points.begin(), points.end());

    std::list<Vertex_handle> vertices;
    T.incident_vertices(T.infinite_vertex(), std::back_inserter(vertices));
    std::cout << "This convex hull of the 250 points has "
              << vertices.size() << " points on it." << std::endl;

    // remove 25 of the input points
    std::list<Vertex_handle>::iterator v_set_it = vertices.begin();
    for (int i = 0; i < 25; i++)
    {
        T.remove(*v_set_it);
        v_set_it++;
    }

    vertices.clear();
    T.incident_vertices(T.infinite_vertex(), std::back_inserter(vertices));
    std::cout << "After removal of 25 points, there are "
              << vertices.size() << " points on the convex hull." << std::endl;
    return 0;
}

```

3D Convex Hulls

Reference Manual

Susan Hert and Stefan Schirra

A subset $S \subseteq \mathbb{R}^3$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S . The convex hull of a set S is the smallest convex set containing S . The convex hull of a set of points P is a convex polytope with vertices in P . A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P .

CGAL provides functions for computing convex hulls in two, three and arbitrary dimensions as well as functions for testing if a given set of points is strongly convex or not. This chapter describes the functions available for three dimensions.

Assertions

The assertion flags for the convex hull and extreme point algorithms use *CH* in their names (e.g., *CGAL_CH_NO_POSTCONDITIONS*). For the convex hull algorithms, the postcondition check tests only convexity (if not disabled), but not containment of the input points in the polygon or polyhedron defined by the output points. The latter is considered an expensive checking and can be enabled by defining *CGAL_CH_CHECK_EXPENSIVE*.

CGAL::convex_hull_3

Definition

The function *convex_hull_3* computes the convex hull of a given set of three-dimensional points. Two versions of this function are available. The first can be used when it is known that the result will be a polyhedron and the second when a degenerate hull may also be possible.

```
#include <CGAL/convex_hull_3.h>
```

```
template <class InputIterator, class Polyhedron_3, class Traits>
void convex_hull_3( InputIterator first,
                   InputIterator last,
                   Polyhedron_3& P,
                   Traits ch_traits = Default_traits)
```

computes the convex hull of the set of points in the range $[first, last)$. The polyhedron P is cleared, then the convex hull is stored in P and the plane equations of each face are computed.

Precondition: : There are at least four points in the range $[first, last)$ not all of which are collinear.

```
template <class InputIterator, class Polyhedron_3, class Traits>
void convex_hull_3( InputIterator first,
                   InputIterator last,
                   Object& ch_object,
                   Traits ch_traits = Default_traits)
```

computes the convex hull of the set of points in the range $[first, last)$. The result, which may be a point, a segment, a triangle, or a polyhedron, is stored in *ch_object*. When the result is a polyhedron, the plane equations of each face are computed.

Requirements

Both functions require the following:

1. *InputIterator::value_type* is equivalent to *Traits::Point_3*.
2. *Traits* is a model of the concept *ConvexHullTraits_3*. When it is known that the input points are not all coplanar, the types *Traits_xy*, *Traits_yx*, and *Traits_yz* need not be provided. For the purposes of checking the postcondition that the convex hull is valid, *Traits* should also be a model of the concept *IsStronglyConvexTraits_3*.

Both functions have an additional requirement for the polyhedron that is to be constructed. For the first version this is that:

- *Polyhedron_3* is a model of `ConvexHullPolyhedron_3`,

and for the second, it is required that

- *Traits* defines a type *Polyhedron_3* that is a model of `ConvexHullPolyhedron_3`.

The default traits class for both versions of *convex_hull_3* is *Convex_hull_traits_3<R>*, with the representation *R* determined by *InputIterator::value_type*.

Implementation

The algorithm implemented by these functions is the quickhull algorithm of Barnard *et al.* [[BDH96](#)].

Example

The following program computes the convex hull of a set of 250 random points chosen from a sphere of radius 100. It then determines if the resulting hull is a segment or a polyhedron. Notice that the traits class is not necessary in the call to *convex_hull_3* but is used in the definition of *Polyhedron_3*.

```
// file: examples/Convex_hull_3/ch_quickhull_3_ex.C

#include <CGAL/Homogeneous.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/copy_n.h>
#include <CGAL/Convex_hull_traits_3.h>
#include <CGAL/convex_hull_3.h>
#include <vector>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float RT;
#endif

typedef CGAL::Homogeneous<RT> K;
typedef CGAL::Convex_hull_traits_3<K> Traits;
typedef Traits::Polyhedron_3 Polyhedron_3;
typedef K::Segment_3 Segment_3;

// define point creator
typedef K::Point_3 Point_3;
typedef CGAL::Creator_uniform_3<double, Point_3> PointCreator;
```

```

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3, PointCreator> gen(100.0);

    // generate 250 points randomly on a sphere of radius 100.0
    // and copy them to a vector
    std::vector<Point_3> points;
    CGAL::copy_n( gen, 250, std::back_inserter(points) );

    // define object to hold convex hull
    CGAL::Object ch_object;

    // compute convex hull
    CGAL::convex_hull_3(points.begin(), points.end(), ch_object);

    // determine what kind of object it is
    Segment_3 segment;
    Polyhedron_3 polyhedron;
    if ( CGAL::assign(segment, ch_object) )
        std::cout << "convex hull is a segment " << std::endl;
    else if ( CGAL::assign( polyhedron, ch_object) )
        std::cout << "convex hull is a polyhedron " << std::endl;
    else
        std::cout << "convex hull error!" << std::endl;

    return 0;
}

```

CGAL::convex_hull_incremental_3

Definition

The function *convex_hull_incremental_3* computes the convex hull polyhedron from a set of given three-dimensional points.

```
#include <CGAL/convex_hull_incremental_3.h>
```

```
template <class InputIterator, class Polyhedron>
void convex_hull_incremental_3( InputIterator first,
                               InputIterator beyond,
                               Polyhedron& P,
                               bool test_correctness = false)
```

computes the convex hull polyhedron of the points in the range $[first, beyond)$ and assigns it to P . If *test_correctness* is set to *true*, the tests described in [MNS⁺96] are used to determine the correctness of the resulting polyhedron.

Requirements

1. *Polyhedron* must provide a type *Polyhedron::Traits* that defines the following types
 - *Polyhedron::Traits::R*, which is a model of the representation class R required by *CGAL::Convex_hull_d_traits_3<R>*
 - *Polyhedron::Traits::Point*
2. *InputIterator::value_type* must be the same as *Polyhedron::Traits::Point*

Implementation

This function uses the d -dimensional convex hull incremental construction algorithm [CMS93] with d fixed to 3. The algorithm requires $O(n^2)$ time in the worst case and $O(n \log n)$ expected time.

Example

The following example computes the convex hull of a set of 250 random points chosen uniformly in a sphere of radius 100.

```
// file: examples/Convex_hull_3/incremental_hull_3_ex.C

#include <CGAL/Homogeneous.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/copy_n.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/convex_hull_incremental_3.h>
#include <vector>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float RT;
#endif

typedef CGAL::Homogeneous<RT> K;
typedef K::Point_3 Point_3;
typedef CGAL::Polyhedron_3< K> Polyhedron;
typedef CGAL::Creator_uniform_3<int, Point_3> Creator;

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3, Creator> gen(100.0);

    std::vector<Point_3> V;
    // generate 250 points randomly on a sphere of radius 100.0 and copy
    // them to a vector
    CGAL::copy_n( gen, 250, std::back_inserter(V) );

    Polyhedron P; // define polyhedron to hold convex hull

    // compute convex hull
    CGAL::convex_hull_incremental_3( V.begin(), V.end(), P, true);

    return 0;
}
```

ConvexHullPolyhedronFacet_3

Definition

The requirements of the facet type of a polyhedron to be built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits>::Facetpage [811](#)

Types

ConvexHullPolyhedronFacet_3::Plane plane equation type stored in facets.

ConvexHullPolyhedronFacet_3::Halfedge_handle
handle to halfedge.

ConvexHullPolyhedronFacet_3::Halfedge_around_facet_circulator
circulator of halfedges around a facet.

Creation

ConvexHullPolyhedronFacet_3 f; default constructor.

Operations

Plane& *f.plane()*
const Plane& *f.plane() const* plane equation.

Halfedge_handle *f.halfedge()* an incident halfedge that points to *f*.
Halfedge_around_facet_circulator

f.facet_begin() circulator of halfedges around the facet (counterclockwise).

ConvexHullPolyhedronHalfedge_3

Definition

The requirements of the halfedge type required for the polyhedron built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits>::Halfedge.....page 813

Creation

ConvexHullPolyhedronHalfedge_3 *h*; default constructor.

Operations

<i>Halfedge_handle</i>	<i>h.opposite()</i>	the opposite halfedge.
------------------------	---------------------	------------------------

<i>Halfedge_handle</i>	<i>h.next()</i>	the next halfedge around the facet.
------------------------	-----------------	-------------------------------------

<i>Halfedge_handle</i>	<i>h.prev()</i>	the previous halfedge around the facet.
------------------------	-----------------	-----------------------------------------

<i>bool</i>	<i>h.is_border()</i> <i>const</i>	is true if <i>h</i> is a border halfedge.
-------------	-----------------------------------	-------------------------------------------

<i>Halfedge_around_facet_circulator</i>	
<i>h.facet_begin()</i>	circulator of halfedges around the facet (counterclockwise).

<i>Vertex_handle</i>	<i>h.vertex()</i>	the incident vertex of <i>h</i> .
----------------------	-------------------	-----------------------------------

<i>Facet_handle</i>	<i>h.facet()</i>	the incident facet of <i>h</i> . If <i>h</i> is a border halfedge the result is default construction of the handle.
---------------------	------------------	---------------------------------------------------------------------------------------------------------------------

ConvexHullPolyhedron_3

Definition

The requirements of the polyhedron type to be built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits> page [799](#)

Types

<i>ConvexHullPolyhedron_3:: Point_3</i>	type of point stored in a vertex
<i>ConvexHullPolyhedron_3:: Vertex</i>	a model of <i>ConvexHullPolyhedronVertex_3</i>
<i>ConvexHullPolyhedron_3:: Halfedge</i>	a model of <i>ConvexHullPolyhedronHalfedge_3</i>
<i>ConvexHullPolyhedron_3:: Facet</i>	a model of <i>ConvexHullPolyhedronFacet_3</i>
<i>ConvexHullPolyhedron_3:: Halfedge_data_structure</i>	halfedge data structure
<i>ConvexHullPolyhedron_3:: Halfedge_handle</i>	handle to halfedge
<i>ConvexHullPolyhedron_3:: Halfedge_iterator</i>	iterator for halfedge
<i>ConvexHullPolyhedron_3:: Facet_handle</i>	handle to facet
<i>ConvexHullPolyhedron_3:: Facet_iterator</i>	iterator for facet

Creation

Only a default constructor is required.

ConvexHullPolyhedron_3 *p*;

Operations

<i>Facet_iterator</i>	<i>p.facets_begin()</i>	iterator over all facets (excluding holes).
<i>Facet_iterator</i>	<i>p.facets_end()</i>	past-the-end iterator.
<i>Halfedge_iterator</i>	<i>p.P.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_iterator</i>	<i>p.P.halfedges_end()</i>	past-the-end iterator.
<i>Halfedge_handle</i>	<i>p.make_tetrahedron(Point_3 p1, Point_3 p2, Point_3 p3, Point_3 p4)</i>	

adds a new tetrahedron to the polyhedral surface with its vertices initialized with *p1*, *p2*, *p3* and *p4*. Returns that halfedge of the tetrahedron which incident vertex is initialized with *p1*, the incident vertex of the next halfedge with *p2*, and the vertex thereafter with *p3*. The remaining fourth vertex is initialized with *p4*.

<i>void</i>	<i>p.erase_facet(Halfedge_handle h)</i>	removes the incident facet of <i>h</i> and changes all halfedges incident to the facet into border edges or removes them from the polyhedral surface if they were already border edges.
<i>Halfedge_handle</i>	<i>p.add_vertex_and_facet_to_border(Halfedge_handle h, Halfedge_handle g)</i>	creates a new facet within the hole incident to <i>h</i> and <i>g</i> by connecting the tip of <i>g</i> with the tip of <i>h</i> with two new halfedges and a new vertex and filling this separated part of the hole with a new facet, such that the new facet is incident to <i>g</i> . Returns the halfedge of the new edge that is incident to the new facet and the new vertex.
<i>Halfedge_handle</i>	<i>p.add_facet_to_border(Halfedge_handle h, Halfedge_handle g)</i>	creates a new facet within the hole incident to <i>h</i> and <i>g</i> by connecting the tip of <i>g</i> with the tip of <i>h</i> with a new halfedge and filling this separated part of the hole with a new facet, such that the new facet is incident to <i>g</i> . Returns the halfedge of the new edge that is incident to the new facet.
<i>Halfedge_handle</i>	<i>p.fill_hole(Halfedge_handle h)</i>	fills a hole with a newly created facet. Makes all border halfedges of the hole denoted by <i>h</i> incident to the new facet. Returns <i>h</i> .
<i>void</i>	<i>p.delegate(Modifier_base<Halfedge_data_structure>& m)</i>	calls the <i>operator()</i> of the modifier <i>m</i> . See <i>Modifier_base</i> in the Support Library Manual for a description of modifier design and its usage.

ConvexHullTraits_3

Definition

Requirements of the traits class to be used with the function *convex_hull_3*.

Types

<i>ConvexHullTraits_3:: Point_3</i>	The point type on which the convex hull algorithm operates
<i>ConvexHullTraits_3:: Plane_3</i>	a 3D plane
<i>ConvexHullTraits_3:: Segment_3</i>	a 3D segment
<i>ConvexHullTraits_3:: Triangle_3</i>	a 3D triangle
<i>ConvexHullTraits_3:: Vector_3</i>	a 3D vector
<i>ConvexHullTraits_3:: Construct_plane_3</i>	Function object type that provides <i>Plane_3 operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which constructs and returns a plane passing through <i>p</i> , <i>q</i> , and <i>r</i> and oriented in a positive sense when seen from the positive side of the plane.
<i>ConvexHullTraits_3:: Construct_segment_3</i>	Function object type that provides <i>Segment_3 operator()(Point_3 p, Point_3 q)</i> , which constructs and returns the segment with source <i>p</i> and target <i>q</i> .
<i>ConvexHullTraits_3:: Construct_triangle_3</i>	Function object type that provides <i>Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which constructs and returns the triangle with vertices <i>p</i> , <i>q</i> , and <i>r</i>
<i>ConvexHullTraits_3:: Construct_vector_3</i>	Function object type that provides <i>Vector_3 operator()(Point_3 p, Point_3 q)</i> , which constructs and returns the vector <i>q-p</i>
<i>ConvexHullTraits_3:: Equal_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q)</i> , which determines if points <i>p</i> and <i>q</i> are equal or not
<i>ConvexHullTraits_3:: Collinear_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which determines if points <i>p</i> , <i>q</i> and <i>r</i> are collinear or not
<i>ConvexHullTraits_3:: Coplanar_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)</i> , which determines if points <i>p</i> , <i>q</i> , <i>r</i> , and <i>s</i> are coplanar or not
<i>ConvexHullTraits_3:: Has_on_positive_side_3</i>	Predicate object type that provides <i>bool operator()(Plane_3 h, Point_3 q)</i> , which determines if the point <i>q</i> is on the positive side of the halfspace <i>h</i>

<i>ConvexHullTraits_3:: Less_distance_to_point_3</i>	Predicate object type that provides a constructor taking a single <i>Point_3</i> object and <i>bool operator()(Point_3 q, Point_3 r)</i> , which returns true iff the distance from <i>q</i> to <i>p</i> is smaller than the distance from <i>r</i> to <i>p</i> , where <i>p</i> is the point passed to the object at construction.
------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>ConvexHullTraits_3:: Less_signed_distance_to_plane_3</i>	Predicate object type that provides <i>bool operator()(Plane_3 p, Point_3 q, Point_3 r)</i> , which returns true iff the signed distance from <i>q</i> to <i>p</i> is smaller than the signed distance from <i>r</i> to <i>p</i>
-------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

To handle the degenerate case when all points are coplanar, the following three types that are default-constructable are necessary:

<i>ConvexHullTraits_3:: Traits_xy</i>	A model of <i>ConvexHullTraits_2</i> for points projected into the <i>xy</i> -plane
---------------------------------------	-------------------------------------------------------------------------------------

<i>ConvexHullTraits_3:: Traits_xz</i>	A model of <i>ConvexHullTraits_2</i> for points projected into the <i>xz</i> -plane
---------------------------------------	-------------------------------------------------------------------------------------

<i>ConvexHullTraits_3:: Traits_yz</i>	A model of <i>ConvexHullTraits_2</i> for points projected into the <i>yz</i> -plane
---------------------------------------	-------------------------------------------------------------------------------------

One also needs the following function object to help choose which of the above traits classes to use:

<i>ConvexHullTraits_3:: Max_coordinate_3</i>	Function object type that provides <i>int operator()(Vector_3 v)</i> , which returns the index (0, 1, or 2 for <i>x</i> , <i>y</i> , or <i>z</i> , respectively) of the coordinate of <i>v</i> with maximum absolute value.
----------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

These types need not be provided when it is known that the points are not all coplanar.

Creation

Only a copy constructor is required.

```
ConvexHullTraits_3 traits( & ch);
```

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

```
Construct_plane_3 traits.construct_plane_3_object()
```

Has Models

CGAL::convex_hull_2 [page 639](#)

CGAL::is_strongly_convex_3

Definition

The function *is_strongly_convex_3* determines if the vertices of a given polyhedron represents a strongly convex set of points or not. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

```
#include <CGAL/convexity_check_3.h>
```

```
template<class Polyhedron_3, class Traits>
bool is_strongly_convex_3( Polyhedron_3& P, Traits traits = Default_traits)
```

determines if the set of vertices of the polyhedron *P* represent a strongly convex set of points or not.

Precondition: The equations of the facet planes of the polyhedron must have already been computed.

The default traits class is the kernel in which the type *Polyhedron_3::Point_3* is defined.

Requirements

1. *Polyhedron_3::Point_3* is equivalent to *Traits::Point_3*.
2. *Traits* is a model of the concept *IsStronglyConvexTraits_3*
3. *Polyhedron_3* must define the following types:

- *Polyhedron_3::Facet_iterator*
- *Polyhedron_3::Vertex_iterator*

and the following member functions:

- *facets_begin()*
- *facets_end()*
- *vertices_begin()*
- *vertices_end()*

The vertex type of *Polyhedron_3* must be a model of *ConvexHullPolyhedronVertex_3*; the facet type must be *ConvexHullPolyhedronFacet_3*.

See Also

CGAL::is_ccw_strongly_convex_2 page 648
CGAL::is_cw_strongly_convex_2 page 649

Implementation

This function implements the tests described in [MNS⁺96] to determine convexity and requires $O(e + f)$ time for a polyhedron with e edges and f faces.

IsStronglyConvexTraits_3

Definition

Requirements of the traits class used by the function *is_strongly_convex_3*, which is used for postcondition checking by *convex_hull_3*.

Types

<i>IsStronglyConvexTraits_3:: Plane_3</i>	a 3D plane
<i>IsStronglyConvexTraits_3:: Point_3</i>	a 3D point
<i>IsStronglyConvexTraits_3:: Ray_3</i>	a 3D ray
<i>IsStronglyConvexTraits_3:: Triangle_3</i>	a 3D triangle
<i>IsStronglyConvexTraits_3:: Construct_ray_3</i>	Function object type that provides <i>Ray_3 operator()(Point_3 p, Point_3 q)</i> , which constructs and returns the ray based at point <i>p</i> and passing through <i>q</i>
<i>IsStronglyConvexTraits_3:: Construct_triangle_3</i>	Function object type that provides <i>Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which constructs and returns the triangle with vertices <i>p</i> , <i>q</i> , and <i>r</i>
<i>IsStronglyConvexTraits_3:: Coplanar_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)</i> , which determines if points <i>p</i> , <i>q</i> , <i>r</i> , and <i>s</i> are coplanar or not
<i>IsStronglyConvexTraits_3:: Do_intersect_3</i>	Function object type that provides <i>CGAL::Object operator()(Triangle_3 t, Ray_3 r)</i> , which returns <i>true</i> iff <i>t</i> and <i>r</i> intersect.
<i>IsStronglyConvexTraits_3:: Has_on_positive_side_3</i>	Predicate object type that provides <i>bool operator()(Plane_3 h, Point_3 q)</i> , which determines if the point <i>q</i> is on the positive side of the halfspace <i>h</i>
<i>IsStronglyConvexTraits_3:: Oriented_side_3</i>	Predicate object type that provides <i>Oriented_side operator()(Plane_3 p, Point_3 q)</i> , which determines the position of point <i>q</i> relative to plane <i>p</i>

Creation

Only a copy constructor is required.

```
IsStronglyConvexTraits_3 traits( & t);
```

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_ray_3 *traits.construct_ray_3_object()*

dD Convex Hulls and Delaunay Triangulations

Susan Hert and Michael Seel

Contents

7.1 Introduction	681
7.2 dD Convex Hull	681
7.3 Delaunay Triangulation	682

7.1 Introduction

A subset $S \subseteq \mathbb{R}^d$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S . The convex hull of a set S is the smallest convex set containing S . The convex hull of a set of points P is a convex polytope with vertices in P . A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P . A set of points is said to be strongly convex if it consist of only extreme points.

This chapter describes the class provided in CGAL for producing convex hull in arbitrary dimensions. There is an intimate relationship between the Delaunay triangulation of a point set S and the convex hull of $lift(S)$: The nearest site Delaunay triangulation is the projection of the lower hull and the furthest site Delaunay triangulation is the upper hull. Here we also describe the companion class to the convex hull class that computes nearest and furthest site Delaunay triangulations.

7.2 dD Convex Hull

The class `CGAL::Convex_hull_d<R>` is used to represent the convex hull of a set of points in d -dimensional space. This class supports incremental construction of hulls, and provides a rich interface for exploration. There are also output routines for hulls of dimension 2 and 3.

The convex hull class is parameterized by a traits class that provides d -dimensional data types and predicates. The class `Convex_hull_d_traits_3` adapts any low-dimensional standard kernel model *e.g.*, `Homogeneous<RT>` or `Cartesian<FT>` for use with `Convex_hull_d`, where the dimension is fixed to three. The validity of the

computed convex hull can be checked using the member function *is_valid*, which implements the algorithm of Mehlhorn *et al.* [MNS⁺96] to determine if the vertices of a given polytope constitute a strongly convex point set or not.

The implementation follows the papers [CMS93] and [BMS94].

7.3 Delaunay Triangulation

There is a class type with a thorough interface providing the construction and exploration of closest and furthest site Delaunay simplicial complexes in arbitrary higher dimension. The class *CGAL::Delaunay_d<R, Lifted_R>* provides an implementation via the lifting map to higher dimensional convex hulls.. The class supports incremental construction of Delaunay triangulations and various kind of query operations (in particular, nearest and furthest neighbor queries and range queries with spheres and simplices).

dD Convex Hulls and Delaunay Triangulations Reference Manual

Susan Hert and Michael Seel

A subset $S \subseteq \mathbb{R}^3$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S . The convex hull of a set S is the smallest convex set containing S . The convex hull of a set of points P is a convex polytope with vertices in P . A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P .

CGAL provides functions for computing convex hulls in two, three and arbitrary dimensions as well as functions for testing if a given set of points is strongly convex or not. This chapter describes the class available for arbitrary dimensions and its companion class for computing the nearest and furthest side Delaunay triangulation.

ConvexHullTraits_d

Definition

Requirements of the traits class to be used with the class *Convex_hull_d*.

Types

<i>ConvexHullTraits_d:: Point_d</i>	the dD point type on which the convex hull algorithm operates
<i>ConvexHullTraits_d:: Hyperplane_d</i>	a dD plane
<i>ConvexHullTraits_d:: Vector_d</i>	a dD vector
<i>ConvexHullTraits_d:: Ray_d</i>	a dD ray
<i>ConvexHullTraits_d:: RT</i>	an arithmetic ring type
<i>ConvexHullTraits_d:: Construct_vector_d</i>	Function object type that provides <i>Vector_d operator()(int d, CGAL::Null_vector)</i> , which constructs and returns the null vector.
<i>ConvexHullTraits_d:: Construct_hyperplane_d</i>	Function object type that provides <i>Hyperplane_d operator()(ForwardIterator first, ForwardIterator last, Point_d p, CGAL::Oriented_side side)</i> , which constructs and returns a hyperplane passing through the points in <i>tuple[first,last)</i> and oriented such that <i>p</i> is on the side <i>side</i> of the returned hyperplane. When <i>side==ON_ORIENTED_BOUNDARY</i> then any hyperplane containing the tuple is returned.
<i>ConvexHullTraits_d:: Vector_to_point_d</i>	Function object type that provides <i>Point_d operator()(Vector_d v)</i> , which constructs and returns the point defined by $0 + v$.
<i>ConvexHullTraits_d:: Point_to_vector_d</i>	Function object type that provides <i>Vector_d operator()(Point_d v)</i> , which constructs and returns the vector defined by $p - 0$.
<i>ConvexHullTraits_d:: Orientation_d</i>	Function object type that provides <i>Orientation operator()(ForwardIterator first, ForwardIterator last)</i> , which determines the orientation of the points <i>tuple[first,last)</i> .
<i>ConvexHullTraits_d:: Orthogonal_vector_d</i>	Function object type that provides <i>Vector_d operator()(Hyperplane_d h)</i> , which constructs and returns a vector orthogonal to <i>h</i> and pointing from the boundary into its positive halfspace.
<i>ConvexHullTraits_d:: Oriented_side_d</i>	Predicate object type that provides <i>Oriented_side operator()(Hyperplane_d h, Point_d p)</i> , which determines the oriented side of <i>p</i> with respect to <i>h</i> .

<i>ConvexHullTraits_d:: Has_on_positive_side_d</i>	Predicate object type that provides <i>bool operator()(Hyperplane_d h, Point_d p)</i> , which return true iff <i>p</i> lies in the positive halfspace determined by <i>h</i> .
<i>ConvexHullTraits_d:: Affinely_independent_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last)</i> , which determines if the points <i>tuple[first,last)</i> are affinely independent.
<i>ConvexHullTraits_d:: Contained_in_simplex_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the closed simplex defined by the points in <i>tuple[first,last)</i> .
<i>ConvexHullTraits_d:: Contained_in_affined_hull_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the affine hull of the points in <i>tuple[first,last)</i> .
<i>ConvexHullTraits_d:: Intersect_d</i>	Predicate object type that provides <i>Object operator()(Ray_d r, Hyperplane_d h)</i> , which determines if <i>r</i> and <i>h</i> intersect and returns the corresponding polymorphic object.

Creation

A default constructor and copy constructor is required.

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_vector_d *traits.construct_vector_d_object()*

CGAL::Convex_hull_d<R>

Definition

An instance C of type *Convex_hull_d<R>* is the convex hull of a multi-set S of points in d -dimensional space. We call S the underlying point set and d or *dim* the dimension of the underlying space. We use d_{cur} to denote the affine dimension of S . The data type supports incremental construction of hulls.

The closure of the hull is maintained as a simplicial complex, i.e., as a collection of simplices. The intersection of any two is a face of both¹. In the sequel we reserve the word simplex for the simplices of dimension d_{cur} . For each simplex there is a handle of type *Simplex_handle* and for each vertex there is a handle of type *Vertex_handle*. Each simplex has $1 + d_{cur}$ vertices indexed from 0 to d_{cur} ; for a simplex s and an index i , $C.vertex(s,i)$ returns the i -th vertex of s . For any simplex s and any index i of s there may or may not be a simplex t opposite to the i -th vertex of s . The function $C.opposite_simplex(s,i)$ returns t if it exists and returns *Simplex_handle()* (the undefined handle) otherwise. If t exists then s and t share d_{cur} vertices, namely all but the vertex with index i of s and the vertex with index $C.index_of_vertex_in_opposite_simplex(s,i)$ of t . Assume that t exists and let $j = C.index_of_vertex_in_opposite_simplex(s,i)$. Then $s = C.opposite_simplex(t,j)$ and $i = C.index_of_vertex_in_opposite_simplex(t,j)$.

The boundary of the hull is also a simplicial complex. All simplices in this complex have dimension $d_{cur} - 1$. For each boundary simplex there is a handle of type *Facet_handle*. Each facet has d_{cur} vertices indexed from 0 to $d_{cur} - 1$. If $d_{cur} > 1$ then for each facet f and each index i , $0 \leq i < d_{cur}$, there is a facet g opposite to the i -th vertex of f . The function $C.opposite_facet(f,i)$ returns g . Two neighboring facets f and g share $d_{cur} - 1$ vertices, namely all but the vertex with index i of f and the vertex with index $C.index_of_vertex_in_opposite_facet(f,i)$ of g . Let $j = C.index_of_vertex_in_opposite_facet(f,i)$. Then $f = C.opposite_facet(g,j)$ and $i = C.index_of_vertex_in_opposite_facet(g,j)$.

Types

<i>Convex_hull_d<R>:: R</i>	the representation class.
<i>Convex_hull_d<R>:: Point_d</i>	the point type.
<i>Convex_hull_d<R>:: Hyperplane_d</i>	the hyperplane type.
<i>Convex_hull_d<R>:: Simplex_handle</i>	handle for simplices.
<i>Convex_hull_d<R>:: Facet_handle</i>	handle for facets.
<i>Convex_hull_d<R>:: Vertex_handle</i>	handle for vertices.
<i>Convex_hull_d<R>:: Simplex_iterator</i>	iterator for simplices.
<i>Convex_hull_d<R>:: Facet_iterator</i>	iterator for facets.
<i>Convex_hull_d<R>:: Vertex_iterator</i>	iterator for vertices.

¹The empty set if a facet of every simplex.

Convex_hull_d<R>:: Hull_vertex_iterator iterator for vertices that are part of the convex hull.

Note that each iterator fits the handle concept, i.e. iterators can be used as handles. Note also that all iterator and handle types come also in a const flavor, e.g., *Vertex_const_iterator* is the constant version of *Vertex_iterator*. Const correctness requires to use the const version whenever the convex hull object is referenced as constant. The *Hull_vertex_iterator* is convertible to *Vertex_iterator* and *Vertex_handle*.

Convex_hull_d<R>:: Point_const_iterator const iterator for all inserted points.

Convex_hull_d<R>:: Hull_point_const_iterator
const iterator for all points that are part of the convex hull.

Creation

Convex_hull_d<R> *C*(*int d*, *R Kernel* = *R*());

creates an instance *C* of type *Convex_hull_d*. The dimension of the underlying space is *d* and *S* is initialized to the empty point set. The traits class *R* specifies the models of all types and the implementations of all geometric primitives used by the convex hull class. The default model is one of the *d*-dimensional representation classes (e.g., *Homogeneous_d*).

The data type *Convex_hull_d* offers neither copy constructor nor assignment operator.

Requirements

R is a model of the concept *ConvexHullTraits_d*.

Operations

All operations below that take a point *x* as argument have the common precondition that *x* is a point of ambient space.

int *C.dimension()*
returns the dimension of ambient space

int *C.current_dimension()*
returns the affine dimension *d_{cur}* of *S*.

Point_d *C.associated_point(Vertex_handle v)*
returns the point associated with vertex *v*.

<i>Vertex_handle</i>	<i>C.vertex_of_simplex(Simplex_handle s, int i)</i>	<p>returns the vertex corresponding to the i-th vertex of s.</p> <p><i>Precondition:</i> $0 \leq i \leq dcur$.</p>
<i>Point_d</i>	<i>C.point_of_simplex(Simplex_handle s, int i)</i>	<p>same as <i>C.associated_point(C.vertex_of_simplex(s,i))</i>.</p>
<i>Simplex_handle</i>	<i>C.opposite_simplex(Simplex_handle s, int i)</i>	<p>returns the simplex opposite to the i-th vertex of s (<i>Simplex_handle()</i> if there is no such simplex).</p> <p><i>Precondition:</i> $0 \leq i \leq dcur$.</p>
<i>int</i>	<i>C.index_of_vertex_in_opposite_simplex(Simplex_handle s, int i)</i>	<p>returns the index of the vertex opposite to the i-th vertex of s.</p> <p><i>Precondition:</i> $0 \leq i \leq dcur$ and there is a simplex opposite to the i-th vertex of s.</p>
<i>Simplex_handle</i>	<i>C.simplex(Vertex_handle v)</i>	<p>returns a simplex of which v is a node. Note that this simplex is not unique.</p>
<i>int</i>	<i>C.index(Vertex_handle v)</i>	<p>returns the index of v in <i>simplex(v)</i>.</p>
<i>Vertex_handle</i>	<i>C.vertex_of_facet(Facet_handle f, int i)</i>	<p>returns the vertex corresponding to the i-th vertex of f.</p> <p><i>Precondition:</i> $0 \leq i < dcur$.</p>
<i>Point_d</i>	<i>C.point_of_facet(Facet_handle f, int i)</i>	<p>same as <i>C.associated_point(C.vertex_of_facet(f,i))</i>.</p>
<i>Facet_handle</i>	<i>C.opposite_facet(Facet_handle f, int i)</i>	<p>returns the facet opposite to the i-th vertex of f (<i>Facet_handle()</i> if there is no such facet).</p> <p><i>Precondition:</i> $0 \leq i < dcur$ and $dcur > 1$.</p>

<i>int</i>	<i>C.index_of_vertex_in_opposite_facet(Facet_handle f, int i)</i> returns the index of the vertex opposite to the i -th vertex of f . <i>Precondition:</i> $0 \leq i < dcur$ and $dcur > 1$.
<i>Hyperplane_d</i>	<i>C.hyperplane_supporting(Facet_handle f)</i> returns a hyperplane supporting facet f . The hyperplane is oriented such that the interior of C is on the negative side of it. <i>Precondition:</i> f is a facet of C and $dcur > 1$.
<i>Vertex_handle</i>	<i>C.insert(Point_d x)</i> adds point x to the underlying set of points. If x is equal to (the point associated with) a vertex of the current hull this vertex is returned and its associated point is changed to x . If x lies outside the current hull, a new vertex v with associated point x is added to the hull and returned. In all other cases, i.e., if x lies in the interior of the hull or on the boundary but not on a vertex, the current hull is not changed and <i>Vertex_handle()</i> is returned. If <i>CGAL_CHECK_EXPENSIVE</i> is defined then the validity check <i>is_valid(true)</i> is executed as a post condition.
<i>template <typename Forward_iterator></i> <i>void</i>	<i>C.insert(Forward_iterator first, Forward_iterator last)</i> adds $S = set [first, last)$ to the underlying set of points. If any point $S[i]$ is equal to (the point associated with) a vertex of the current hull its associated point is changed to $S[i]$.
<i>bool</i>	<i>C.is_dimension_jump(Point_d x)</i> returns true if x is not contained in the affine hull of S .
<i>std::list<Facet_handle></i>	<i>C.facets_visible_from(Point_d x)</i> returns the list of all facets that are visible from x . <i>Precondition:</i> x is contained in the affine hull of S .
<i>Bounded_side</i>	<i>C.bounded_side(Point_d x)</i> returns <i>ON_BOUNDED_SIDE</i> (<i>ON_BOUNDARY</i> , <i>ON_UNBOUNDED_SIDE</i>) if x is contained in the interior (lies on the boundary, is contained in the exterior) of C . <i>Precondition:</i> x is contained in the affine hull of S .

<i>void</i>	<i>C.clear(int d)</i>	reinitializes <i>C</i> to an empty hull in <i>d</i> -dimensional space.
<i>int</i>	<i>C.number_of_vertices()</i>	returns the number of vertices of <i>C</i> .
<i>int</i>	<i>C.number_of_facets()</i>	returns the number of facets of <i>C</i> .
<i>int</i>	<i>C.number_of_simplices()</i>	returns the number of bounded simplices of <i>C</i> .
<i>void</i>	<i>C.print_statistics()</i>	gives information about the size of the current hull and the number of visibility tests performed.
<i>bool</i>	<i>C.is_valid(bool throw_exceptions = false)</i>	checks the validity of the data structure. If <i>throw_exceptions == true</i> then the program throws the following exceptions to inform about the problem. <i>chull_has_center_on_wrong_side_of_hull_facet</i> the hyperplane supporting a facet has the wrong orientation. <i>chull_has_local_non_convexity</i> a ridge is locally non convex. <i>chull_has_double_coverage</i> the hull has a winding number larger than 1.

Lists and Iterators

<i>Vertex_iterator</i>	<i>C.vertices_begin()</i>	an iterator of <i>C</i> to start the iteration over all vertices of the complex.
<i>Vertex_iterator</i>	<i>C.vertices_end()</i>	the past the end iterator for vertices.
<i>Simplex_iterator</i>	<i>C.simplices_begin()</i>	an iterator of <i>C</i> to start the iteration over all simplices of the complex.
<i>Simplex_iterator</i>	<i>C.simplices_end()</i>	the past the end iterator for simplices.
<i>Facet_iterator</i>	<i>C.facets_begin()</i>	an iterator of <i>C</i> to start the iteration over all facets of the complex.

<i>Facet_iterator</i>	<i>C.facets_end()</i>	the past the end iterator for facets.
<i>Hull_vertex_iterator</i>	<i>C.hull_vertices_begin()</i>	an iterator to start the iteration over all vertices of <i>C</i> that are part of the convex hull.
<i>Hull_vertex_iterator</i>	<i>C.hull_vertices_end()</i>	the past the end iterator for hull vertices.
<i>Point_const_iterator</i>	<i>C.points_begin()</i>	returns the start iterator for all points that have been inserted to construct <i>C</i> .
<i>Point_const_iterator</i>	<i>C.points_end()</i>	returns the past the end iterator for points.
<i>Hull_point_const_iterator</i>	<i>C.hull_points_begin()</i>	returns an iterator to start the iteration over all points in the convex hull <i>C</i> . Included are points in the interior of facets.
<i>Hull_point_const_iterator</i>	<i>C.hull_points_end()</i>	returns the past the end iterator for points in the convex hull.
<i>template <typename Visitor></i> <i>void</i>	<i>C.visit_all_facets(Visitor V)</i>	each facet of <i>C</i> is visited by the visitor object <i>V</i> . <i>V</i> has to have a function call operator: <i>void operator()(Facet_handle) const</i>
<i>std::list<Point_d></i>	<i>C.all_points()</i>	returns a list of all points that have been inserted to construct <i>C</i> .
<i>std::list<Vertex_handle></i>	<i>C.all_vertices()</i>	returns a list of all vertices of <i>C</i> (also interior ones).
<i>std::list<Simplex_handle></i>	<i>C.all_simplices()</i>	returns a list of all simplices in <i>C</i> .
<i>std::list<Facet_handle></i>	<i>C.all_facets()</i>	returns a list of all facets of <i>C</i> .

Iteration Statements

forall_ch_vertices(v, C) { “the vertices of C are successively assigned to v ” }

forall_ch_simplices(s, C) { “the simplices of C are successively assigned to s ” }

forall_ch_facets(f, C) { “the facets of C are successively assigned to f ” }

Implementation

The implementation of type *Convex_hull_d* is based on [CMS93] and [BMS94]. The details of the implementation can be found in the implementation document available at the download site of this package.

The time and space requirements are input dependent. Let C_1, C_2, C_3, \dots be the sequence of hulls constructed and for a point x let k_i be the number of facets of C_i that are visible from x and that are not already facets of C_{i-1} . Then the time for inserting x is $O(\dim \sum_i k_i)$ and the number of new simplices constructed during the insertion of x is the number of facets of the hull which were not already facets of the hull before the insertion.

The data type *Convex_hull_d* is derived from *Regular_complex_d*. The space requirement of regular complexes is essentially $12(\dim + 2)$ bytes times the number of simplices plus the space for the points. *Convex_hull_d* needs an additional $8 + (4 + x)\dim$ bytes per simplex where x is the space requirement of the underlying number type and an additional 12 bytes per point. The total is therefore $(16 + x)\dim + 32$ bytes times the number of simplices plus $28 + x \cdot \dim$ bytes times the number of points.

Low Dimensional Conversion Routine

```
include <CGAL/Convex_hull_d_to_polyhedron_3.h>
```

```
template <class R, class T, class HDS>
void convex_hull_d_to_polyhedron_3( C, Polyhedron_3<T,HDS>& P)
```

converts the convex hull C to polyedral surface stored in P .

Precondition: $\dim == 3$ and $dcur == 3$.

Low Dimensional Output Routines

```
include <CGAL/IO/Convex_hull_d_window_stream.h>
```

```
template <class R>
void d2_show( C, CGAL::Window_stream& W)
```

draws the convex hull C in window W .

Precondition: $\dim == 2$.

```
template <class R>
void d3_surface_map( C, GRAPH< typename ::Point_d ,int>& G)
```

constructs the representation of the surface of C as a bidi-rected LEDA graph G .

Precondition: $\dim == 3$.

CGAL::Convex_hull_d_traits_3<R>

Definition

The class *Convex_hull_d_traits_3<R>* serves as a traits class for the class *Convex_hull_d*. This is a traits class that adapts any low-dimensional standard kernel model, e.g. *Homogeneous<RT>* or *Cartesian<FT>* for the fixed 3-dimensional usage of *Convex_hull_d*.

```
#include <CGAL/Convex_hull_d_traits_3.h>
```

Is Model for the Concepts

ConvexHullTraits_d

Creation

Convex_hull_d_traits_3<R> traits; default constructor.

DelaunayLiftedTraits_d

Definition

Requirements of the second traits class to be used with the class *Delaunay_d*.

Types

<i>DelaunayLiftedTraits_d:: Point_d</i>	the dD point type on which the Delaunay algorithm operates
<i>DelaunayLiftedTraits_d:: Hyperplane_d</i>	a dD plane
<i>DelaunayLiftedTraits_d:: Vector_d</i>	a dD vector
<i>DelaunayLiftedTraits_d:: Ray_d</i>	a dD ray
<i>DelaunayLiftedTraits_d:: RT</i>	a arithmetic ring type
<i>DelaunayLiftedTraits_d:: Construct_vector_d</i>	Function object type that provides <i>Vector_d operator()(int d, CGAL::Null_vector)</i> , which constructs and returns the null vector.
<i>DelaunayLiftedTraits_d:: Construct_hyperplane_d</i>	Function object type that provides <i>Hyperplane_d operator()(ForwardIterator first, ForwardIterator last, Point_d p, CGAL::Oriented_side side)</i> , which constructs and returns a hyperplane passing through the points in <i>tuple[first,last)</i> and oriented such that <i>p</i> is on the side <i>side</i> of the returned hyperplane. When <i>side==ON_ORIENTED_BOUNDARY</i> then any hyperplane containing the tuple is returned.
<i>DelaunayLiftedTraits_d:: Vector_to_point_d</i>	Function object type that provides <i>Point_d operator()(Vector_d v)</i> , which constructs and returns the point defined by $0 + v$.
<i>DelaunayLiftedTraits_d:: Point_to_vector_d</i>	Function object type that provides <i>Vector_d operator()(Point_d p)</i> , which constructs and returns the vector defined by $p - 0$.
<i>DelaunayLiftedTraits_d:: Orientation_d</i>	Function object type that provides <i>Orientation operator()(ForwardIterator first, ForwardIterator last)</i> , which determines the orientation of the points <i>tuple[first,last)</i> .
<i>DelaunayLiftedTraits_d:: Orthogonal_vector_d</i>	Function object type that provides <i>Vector_d operator()(Hyperplane_d h)</i> , which constructs and returns a vector orthogonal to <i>h</i> and pointing from the boundary into its positive halfspace.
<i>DelaunayLiftedTraits_d:: Oriented_side_d</i>	Predicate object type that provides <i>Oriented_side operator()(Hyperplane_d h, Point_d p)</i> , which determines the oriented side of <i>p</i> with respect to <i>h</i> .

<i>DelaunayLiftedTraits_d:: Has_on_positive_side_d</i>	Predicate object type that provides <i>bool operator()(Hyperplane_d h, Point_d p)</i> , which return true iff p lies in the positive halfspace determined by h .
<i>DelaunayLiftedTraits_d:: Affinely_independent_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last)</i> , which determines if the points <i>tuple[first,last)</i> are affinely independent.
<i>DelaunayLiftedTraits_d:: Contained_in_simplex_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if p is contained in the closed simplex defined by the points in <i>tuple[first,last)</i> .
<i>DelaunayLiftedTraits_d:: Contained_in_affined_hull_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if p is contained in the affine hull of the points in <i>tuple[first,last)</i> .
<i>DelaunayLiftedTraits_d:: Intersect_d</i>	Predicate object type that provides <i>Object operator()(Ray_d r, Hyperplane_d h)</i> , which determines if r and h intersect and returns the corresponding polymorphic object.
The previous requirements are all identical to the concept <i>ConvexHullTraits_d</i> . The Delaunay class adds the following requirements.	
<i>DelaunayLiftedTraits_d:: Project_along_d_axis_d</i>	Predicate object type that provides <i>DelaunayTraits_d::Point_d operator()(Point_d p)</i> , which determines the $d - 1$ -dimensional point from the d -dimensional point p while discarding the last coordinate.
<i>DelaunayLiftedTraits_d:: Lift_to_paraboloid_d</i>	Predicate object type that provides <i>Point_d operator()(DelaunayTraits_d::Point_d p)</i> , which determines the d -dimensional point from the $d - 1$ -dimensional point p while lifting it to the paraboloid of revolution.
<i>DelaunayLiftedTraits_d:: Component_accessor_d</i>	Predicate object type that provides <i>RT homogeneous(Vector_d v,int i)</i> and <i>int dimension(Vector_d v)</i> , where the former determines the i th coordinate of v and the latter the dimension of v .

Creation

A default constructor and copy constructor is required.

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_vector_d *traits.construct_vector_d_object()*

Has Models

CGAL::Cartesian_d<FT,LA>
CGAL::Homogeneous_d<RT,LA>

DelaunayTraits_d

Definition

Requirements of the first traits class to be used with the class *Delaunay_d*.

Types

<i>DelaunayTraits_d:: Point_d</i>	the dD point type on which the delaunay algorithm operates
<i>DelaunayTraits_d:: Sphere_d</i>	a dD sphere
<i>DelaunayTraits_d:: FT</i>	an arithmetic field type
<i>DelaunayTraits_d:: Point_of_sphere_d</i>	Predicate object type that provides <i>Point_d operator()(Sphere_d s, int i)</i> , which returns the <i>i</i> th point defining sphere <i>s</i> .
<i>DelaunayTraits_d:: Construct_sphere_d</i>	Predicate object type that provides <i>Sphere_d operator()(int d, ForwardIterator first, ForwardIterator last)</i> , which returns a dD sphere through the points in <i>tuple[first,last)</i> .
<i>DelaunayTraits_d:: Contained_in_simplex_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the closed simplex defined by the points in <i>tuple[first,last)</i> .
<i>DelaunayTraits_d:: Squared_distance_d</i>	Predicate object type that provides <i>FT operator()(Point_d p, Point_d q)</i> , which determines the squared distance from <i>p</i> to <i>q</i> .
<i>DelaunayTraits_d:: Affinely_independent_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last)</i> , which determines if the points in <i>tuple[first,last)</i> are affinely independent.

Creation

A default constructor and copy constructor is required.

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_sphere_d *traits.construct_sphere_d_object()*

Has Models

CGAL::Cartesian_d<FT,LA>

CGAL::Homogeneous_d<RT,LA>

CGAL::Delaunay_d< R, Lifted_R >

Definition

An instance DT of type $Delaunay_d< R, Lifted_R >$ is the nearest and furthest site Delaunay triangulation of a set S of points in some d -dimensional space. We call S the underlying point set and d or dim the dimension of the underlying space. We use $dcur$ to denote the affine dimension of S . The data type supports incremental construction of Delaunay triangulations and various kind of query operations (in particular, nearest and furthest neighbor queries and range queries with spheres and simplices).

A Delaunay triangulation is a simplicial complex. All simplices in the Delaunay triangulation have dimension $dcur$. In the nearest site Delaunay triangulation the circumsphere of any simplex in the triangulation contains no point of S in its interior. In the furthest site Delaunay triangulation the circumsphere of any simplex contains no point of S in its exterior. If the points in S are co-circular then any triangulation of S is a nearest as well as a furthest site Delaunay triangulation of S . If the points in S are not co-circular then no simplex can be a simplex of both triangulations. Accordingly, we view DT as either one or two collection(s) of simplices. If the points in S are co-circular there is just one collection: the set of simplices of some triangulation. If the points in S are not co-circular there are two collections. One collection consists of the simplices of a nearest site Delaunay triangulation and the other collection consists of the simplices of a furthest site Delaunay triangulation.

For each simplex of maximal dimension there is a handle of type *Simplex_handle* and for each vertex of the triangulation there is a handle of type *Vertex_handle*. Each simplex has $1 + dcur$ vertices indexed from 0 to $dcur$. For any simplex s and any index i , $DT.vertex_of(s,i)$ returns the i -th vertex of s . There may or may not be a simplex t opposite to the vertex of s with index i . The function $DT.opposite_simplex(s,i)$ returns t if it exists and returns *Simplex_handle()* otherwise. If t exists then s and t share $dcur$ vertices, namely all but the vertex with index i of s and the vertex with index $DT.index_of_vertex_in_opposite_simplex(s,i)$ of t . Assume that $t = DT.opposite_simplex(s,i)$ exists and let $j = DT.index_of_vertex_in_opposite_simplex(s,i)$. Then $s = DT.opposite_simplex(t,j)$ and $i = DT.index_of_vertex_in_opposite_simplex(t,j)$. In general, a vertex belongs to many simplices.

Any simplex of DT belongs either to the nearest or to the furthest site Delaunay triangulation or both. The test $DT.simplex_of_nearest(dt_simplex\ s)$ returns true if s belongs to the nearest site triangulation and the test $DT.simplex_of_furthest(dt_simplex\ s)$ returns true if s belongs to the furthest site triangulation.

Inherits From

Convex_hull_d<Lifted_R>

Types

<i>Delaunay_d< R, Lifted_R >:: Simplex_handle</i>	handles to the simplices of the complex.
<i>Delaunay_d< R, Lifted_R >:: Vertex_handle</i>	handles to vertices of the complex.
<i>Delaunay_d< R, Lifted_R >:: Point_d</i>	the point type
<i>Delaunay_d< R, Lifted_R >:: Sphere_d</i>	the sphere type

```
enum Delaunay_voronoi_kind { NEAREST, FURTHEST};
```

```
interface flags
```

To use these types you can typedef them into the global scope after instantiation of the class. We use *Vertex_handle* instead of *Delaunay_d< R, Lifted_R >::Vertex_handle* from now on. Similarly we use *Simplex_handle*.

Delaunay_d< R, Lifted_R >:: Point_const_iterator the iterator for points.

Delaunay_d< R, Lifted_R >:: Vertex_iterator the iterator for vertices.

Delaunay_d< R, Lifted_R >:: Simplex_iterator the iterator for simplices.

Creation

```
Delaunay_d< R, Lifted_R > DT( int d, R k1 = R(), Lifted_R k2 = Lifted_R());
```

creates an instance *DT* of type *Delaunay_d*. The dimension of the underlying space is *d* and *S* is initialized to the empty point set. The traits class *R* specifies the models of all types and the implementations of all geometric primitives used by the Delaunay class. The traits class *Lifted_R* specifies the models of all types and the implementations of all geometric primitives used by the base class of *Delaunay_d< R, Lifted_R >*. The second template parameter defaults to the first: *Delaunay_d<R> = Delaunay_d<R, Lifted_R = R >*.

The data type *Delaunay_d* offers neither copy constructor nor assignment operator.

Requirements

R is a model of the concept *DelaunayTraits_d* . *Lifted_R* is a model of the concept *DelaunayLiftedTraits_d* .

Operations

All operations below that take a point *x* as an argument have the common precondition that *x.dimension()* = *DT.dimension()*.

int *DT.dimension()* returns the dimension of ambient space

int *DT.current_dimension()*

returns the affine dimension of the current point set, i.e., -1 if *S* is empty, 0 if *S* consists of a single point, 1 if all points of *S* lie on a common line, etcetera.

bool *DT.is_simplex_of_nearest(Simplex_handle s)*

returns true if *s* is a simplex of the nearest site triangulation.

<i>bool</i>	<i>DT.is_simplex_of_furthest(Simplex_handle s)</i>	returns true if <i>s</i> is a simplex of the furthest site triangulation.
<i>Vertex_handle</i>	<i>DT.vertex_of_simplex(Simplex_handle s, int i)</i>	returns the vertex associated with the <i>i</i> -th node of <i>s</i> . <i>Precondition:</i> $0 \leq i \leq d_{cur}$.
<i>Point_d</i>	<i>DT.associated_point(Vertex_handle v)</i>	returns the point associated with vertex <i>v</i> .
<i>Point_d</i>	<i>DT.point_of_simplex(Simplex_handle s, int i)</i>	returns the point associated with the <i>i</i> -th vertex of <i>s</i> . <i>Precondition:</i> $0 \leq i \leq d_{cur}$.
<i>Simplex_handle</i>	<i>DT.opposite_simplex(Simplex_handle s, int i)</i>	returns the simplex opposite to the <i>i</i> -th vertex of <i>s</i> (<i>Simplex_handle()</i> if there is no such simplex). <i>Precondition:</i> $0 \leq i \leq d_{cur}$.
<i>int</i>	<i>DT.index_of_vertex_in_opposite_simplex(Simplex_handle s, int i)</i>	returns the index of the vertex opposite to the <i>i</i> -th vertex of <i>s</i> . <i>Precondition:</i> $0 \leq i \leq d_{cur}$.
<i>Simplex_handle</i>	<i>DT.simplex(Vertex_handle v)</i>	returns a simplex of the nearest site triangulation incident to <i>v</i> .
<i>int</i>	<i>DT.index(Vertex_handle v)</i>	returns the index of <i>v</i> in <i>DT.simplex(v)</i> .
<i>bool</i>	<i>DT.contains(Simplex_handle s, Point_d x)</i>	returns true if <i>x</i> is contained in the closure of simplex <i>s</i> .
<i>bool</i>	<i>DT.empty()</i>	decides whether <i>DT</i> is empty.
<i>void</i>	<i>DT.clear()</i>	reinitializes <i>DT</i> to the empty Delaunay triangulation.

<i>Vertex_handle</i>	<i>DT.insert(Point_d x)</i>	inserts point x into DT and returns the corresponding <i>Vertex_handle</i> . More precisely, if there is already a vertex v in DT positioned at x (i.e., <i>associated_point</i> (v) is equal to x) then <i>associated_point</i> (v) is changed to x (i.e., <i>associated_point</i> (v) is made identical to x) and if there is no such vertex then a new vertex v with <i>associated_point</i> (v) = x is added to DT . In either case, v is returned.
<i>Simplex_handle</i>	<i>DT.locate(Point_d x)</i>	returns a simplex of the nearest site triangulation containing x in its closure (returns <i>Simplex_handle</i> () if x lies outside the convex hull of S).
<i>Vertex_handle</i>	<i>DT.lookup(Point_d x)</i>	if DT contains a vertex v with <i>associated_point</i> (v) = x the result is v otherwise the result is <i>Vertex_handle</i> ().
<i>Vertex_handle</i>	<i>DT.nearest_neighbor(Point_d x)</i>	computes a vertex v of DT that is closest to x , i.e., $\text{dist}(x, \text{associated_point}(v)) = \min\{\text{dist}(x, \text{associated_point}(u)) \mid u \in S\}.$
<i>std::list<Vertex_handle></i>	<i>DT.range_search(Sphere_d C)</i>	returns the list of all vertices contained in the closure of sphere C .
<i>std::list<Vertex_handle></i>	<i>DT.range_search(std::vector<Point_d> A)</i>	returns the list of all vertices contained in the closure of the simplex whose corners are given by A . <i>Precondition:</i> A must consist of $d + 1$ affinely independent points in base space.
<i>std::list<Simplex_handle></i>	<i>DT.all_simplices(Delaunay_voronoi_kind k = NEAREST)</i>	returns a list of all simplices of either the nearest or the furthest site Delaunay triangulation of S .

std::list<Vertex_handle>

DT.all_vertices(Delaunay_voronoi_kind k = NEAREST)

returns a list of all vertices of either the nearest or the furthest site Delaunay triangulation of *S*.

std::list<Point_d>

DT.all_points()

returns *S*.

Point_const_iterator

DT.points_begin()

returns the start iterator for points in *DT*.

Point_const_iterator

DT.points_end()

returns the past the end iterator for points in *DT*.

Simplex_iterator

DT.simplices_begin(Delaunay_voronoi_kind k = NEAREST)

returns the start iterator for simplices of *DT*.

Simplex_iterator

DT.simplices_end()

returns the past the end iterator for simplices of *DT*.

Implementation

The data type is derived from *Convex_hull_d* via the lifting map. For a point *x* in *d*-dimensional space let *lift(x)* be its lifting to the unit paraboloid of revolution. There is an intimate relationship between the Delaunay triangulation of a point set *S* and the convex hull of *lift(S)*: The nearest site Delaunay triangulation is the projection of the lower hull and the furthest site Delaunay triangulation is the upper hull. For implementation details we refer the reader to the implementation report available from the CGAL server.

The space requirement is the same as for convex hulls. The time requirement for an insert is the time to insert the lifted point into the convex hull of the lifted points.

Example

The abstract data type *Delaunay_d* has a default instantiation by means of the *d*-dimensional geometric kernel.

```
#include <CGAL/Homogeneous_d.h>
#include <CGAL/leda_integer.h>
#include <CGAL/Delaunay_d.h>

typedef leda_integer RT;
typedef CGAL::Homogeneous_d<RT> Kernel;
typedef CGAL::Delaunay_d<Kernel> Delaunay_d;
typedef Delaunay_d::Point_d Point;
typedef Delaunay_d::Simplex_handle Simplex_handle;
typedef Delaunay_d::Vertex_handle Vertex_handle;

int main()
{
    Delaunay_d T(2);
    Vertex_handle v1 = T.insert(Point_d(2,11));
    ...
}
```

Traits requirements

Delaunay_d< *R*, *Lifted_R* > requires the following types from the kernel traits *Lifted_R*:

RT Point_d Vector_d Ray_d Hyperplane_d

and uses the following function objects from the kernel traits:

Construct_hyperplane_d
Construct_vector_d
Vector_to_point_d / Point_to_vector_d
Orientation_d
Orthogonal_vector_d
Oriented_side_d / Has_on_positive_side_d
Affinely_independent_d
Contained_in_simplex_d
Contained_in_affine_hull_d
Intersect_d
Lift_to_paraboloid_d / Project_along_d_axis_d
Component_accessor_d

Delaunay_d< *R*, *Lifted_R* > requires the following types from the kernel traits *R*:

FT Point_d Sphere_d

and uses the following function objects from the kernel traits *R*:

Construct_sphere_d
Squared_distance_d
Point_of_sphere_d
Affinely_independent_d
Contained_in_simplex_d

Low Dimensional Output Routines

include <CGAL/IO/Delaunay_d_window_stream.h>

template <typename *R*, typename *Lifted_R*>

template <typename *R*, typename *Lifted_R*> void

d2_show(*Delaunay_d*<*R*,*Lifted_R*> *D*,
CGAL::Window_stream& *W*,
typename *Delaunay_d*<*R*,*Lifted_R*>::Delaunay_voronoi_kind *k* = *Delaunay_d*<*R*,*Lifted_R*>::NEAREST)

draws the underlying simplicial complex *D* into window *W*.

Precondition: *dim* == 2.

template <typename *R*, typename *Lifted_R*>

```
template <typename R, typename Lifted_R> void
```

```
    d2_map( Delaunay_d<R,Lifted_R> D,
            GRAPH< typename Delaunay_d<R,Lifted_R>::Point_d, int > & DTG,
            typename Delaunay_d<R,Lifted_R>::Delaunay_voronoi_kind k = Delaunay_
d<R,Lifted_R>::NEAREST)
```

constructs a LEDA graph representation of the nearest (*kind* = *NEAREST* or the furthest (*kind* = *FURTHEST*) site Delaunay triangulation.

Precondition: *dim()* == 2.

Part IV

Polygons and Polyhedra

Chapter 8

2D Polygons

Geert-Jan Giezeman and Wieger Wesselink

8.1 Introduction

A polygon is a closed chain of edges. Several algorithms are available for polygons. For some of those algorithms, it is necessary that the polygon is simple. A polygon is simple if edges don't intersect, except consecutive edges, which intersect in their common vertex.

The following algorithms are available:

- find the leftmost, rightmost, topmost and bottommost vertex.
- compute the (signed) area.
- check if a polygon is simple.
- check if a polygon is convex.
- find the orientation (clockwise or counterclockwise)
- check if a point lies inside a polygon.

All those operations take two forward iterators as parameters in order to describe the polygon. These parameters have a point type as value type.

The type *Polygon_2* can be used to represent polygons. Polygons are dynamic. Vertices can be modified, inserted and erased. They provide the algorithms described above as member functions. Moreover, they provide ways of iterating over the vertices and edges.

Currently, the *Polygon_2* class is a nice wrapper around the algorithms, but little more. Especially, computed values are not cached. That is, when the *is_simple()* member function is called twice or more, the result is computed each time anew. It is possible to set a preprocessor flag to alter this behaviour. In the future, caching will become the default.

8.2 Example

The following code fragment creates a polygon and does some checks.

```

// file: examples/Polygon/Polygon.C

#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

typedef CGAL::Cartesian<double> K;
typedef K::Point_2 Point;
typedef CGAL::Polygon_2<K> Polygon;
using std::cout; using std::endl;

int main()
{
    Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6) };
    Polygon pgn(points, points+4);

    // check if the polygon is simple.
    cout << "The polygon is " <<
        (pgn.is_simple() ? " " : "not ") << "simple." << endl;

    // check if the polygon is convex
    cout << "The polygon is " <<
        (pgn.is_convex() ? " " : "not ") << "convex." << endl;

    return 0;
}

```

```

// file: examples/Polygon/polygon_algorithms.C

#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2_algorithms.h>
#include <iostream>

typedef CGAL::Cartesian<double> K;
typedef K::Point_2 Point;
using std::cout; using std::endl;

void check_inside(Point pt, Point *pgn_begin, Point *pgn_end, K traits)
{
    cout << "The point " << pt;
    switch(CGAL::bounded_side_2(pgn_begin, pgn_end, pt, traits)) {
        case CGAL::ON_BOUNDED_SIDE :
            cout << " is inside the polygon.\n";
            break;
        case CGAL::ON_BOUNDARY:
            cout << " is on the polygon boundary.\n";
            break;
        case CGAL::ON_UNBOUNDED_SIDE:
            cout << " is outside the polygon.\n";
            break;
    }
}

```

Figure 8.1: A polygon and some points

```

}

int main()
{
    Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6)};

    // check if the polygon is simple.
    cout << "The polygon is "
        << (CGAL::is_simple_2(points, points+4, K()) ? "" : "not ")
        << "simple." << endl;

    check_inside(Point(0.5, 0.5), points, points+4, K());
    check_inside(Point(1.5, 2.5), points, points+4, K());
    check_inside(Point(2.5, 0), points, points+4, K());

    return 0;
}

```

2D Polygons

Reference Manual

Geert-Jan Giezeman and Wiegner Wesselink

Assertions

The assertion flags for the polygons and polygon operations use *POLYGON* in their names (e.g., *CGAL_POLYGON_NO_ASSERTIONS*).

CGAL::area_2

Definition

The function *area_2* computes the signed area of a polygon.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
void      area_2( ForwardIterator first,
                  ForwardIterator last,
                  typename Traits::FT &result,
                  Traits traits)
```

Computes the signed area of the polygon defined by the range of points *first* ... *last*. The area is returned in the parameter *result*. The sign is positive for counterclockwise polygons, negative for clockwise polygons. If the polygon is not simple, the area is not well defined. The functionality is also available by the *polygon_area_2* function, which returns the area instead of taking it as a parameter.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
 - *Compute_area_2* : Computes the signed area of the oriented triangle defined by 3 *Point_2* passed as arguments.
 - *FT*
 - *compute_area_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

CGAL::bbox_2

Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class InputIterator, class Traits>
Bbox_2          bbox_2( InputIterator first, InputIterator last, Traits traits)
```

Returns the bounding box of the range $[first, last)$.

Requirements

1. *Traits* is a model of the concept `PolygonTraits_2`. In fact, only the members *Construct_bbox_2* and *construct_bbox_2_object* are used.
2. *InputIterator::value_type* should be *Traits::Point_2*,

See Also

CGAL::Polygon_2<PolygonTraits_2, Container> page [726](#)

CGAL::bottom_vertex_2

Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator bottom_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the bottommost point from the range $[first, last)$. In case of a tie, the point with the smallest x -coordinate is taken.

Requirements

1. *Traits* is a model of the concept `PolygonTraits_2`. In fact, only the members `Less_yx_2` and `less_yx_2_object` are used.
2. `ForwardIterator::value_type` should be `Traits::Point_2`,

`PolygonTraits_2` page [724](#)

Example

CGAL::bounded_side_2

Definition

The function *bounded_side_2* computes if a point lies inside a polygon.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
Bounded_side          bounded_side_2( ForwardIterator first,
                                      ForwardIterator last,
                                      Traits::Point_2 point,
                                      Traits traits)
```

The function *bounded_side_2* computes if a point lies inside a polygon. The polygon is defined by the sequence of points *first*...*last*. Being inside is defined by the odd-even rule. If we take a ray starting at the point and extending to infinity (in any direction), we count the number of intersections. If this number is odd, the point is inside, otherwise it is outside. If the point is on a polygon edge, a special value is returned. A simple polygon divides the plane in an unbounded and a bounded region. According to the definition points in the bounded region are inside the polygon.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:

- *Compare_x_2*
- *Compare_y_2*
- *Orientation_2*
- *compare_x_2_object*
- *compare_y_2_object*
- *orientation_2_object*

2. *ForwardIterator::value_type* should be *Traits::Point_2*,

Implementation

The running time is linear in the number of vertices of the polygon. A horizontal ray is taken to count the number of intersections. Special care is taken that the result is correct even if there are degeneracies (if the ray passes through a vertex).

CGAL::Bounded_side

CGAL::is_convex_2

Definition

The function *is_convex_2* computes if a polygon is convex.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
bool is_convex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
 - *Less_xy_2*
 - *Orientation_2*
 - *less_xy_2_object*
 - *orientation_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

See Also

PolygonTraits_2 page [724](#)
CGAL::Polygon_2<*PolygonTraits_2*, *Container*> page [726](#)

CGAL::is_simple_2

Definition

The function *is_simple_2* computes if a polygon is simple, that is, does not self-intersect.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
inline bool is_simple_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

A polygon is called simple if the edges do not intersect, except consecutive edge in their common vertex. This function checks if the polygon defined by the range *first* ... *last* is simple.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
 - *Point_2*
 - *Less_xy_2*
 - *Orientation_2*
 - *less_xy_2*
 - *orientation_2*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

Implementation

The simplicity test is implemented by means of a plane sweep algorithm. The algorithm is quite robust when used with inexact number types. The running time is $O(n \log n)$, where n is the number of vertices of the polygon.

CGAL::left_vertex_2

Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator left_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the leftmost point from the range $[first, last)$. In case of a tie, the point with the smallest y-coordinate is taken.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. In fact, only the members *Less_xy_2* and *less_xy_2_object* are used.
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

CGAL::orientation_2

Definition

The function *orientation_2* computes if a polygon is clockwise or counterclockwise oriented.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
Orientation          orientation_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Precondition: *is_simple_2*(first, last, traits);

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
 - *Less_xy_2*
 - *less_xy_2_object*
 - *orientation_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

CGAL::oriented_side_2

Definition

The function *oriented_side_2* computes on which side of a polygon a point lies.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
Oriented_side          oriented_side_2( ForwardIterator first,
                                       ForwardIterator last,
                                       Traits::Point_2 point,
                                       Traits traits)
```

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
 - *Less_xy_2*
 - *Compare_x_2*
 - *Compare_y_2*
 - *Orientation_2*
 - *less_xy_2_object*
 - *compare_x_2_object*
 - *compare_y_2_object*
 - *orientation_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

PolygonTraits_2

Definition

The *Polygon_2* class and the functions that implement the functionality found in that class each are parameterized by a traits class that defines the primitives used in the algorithms. The concept *PolygonTraits_2* defines this common set of requirements.

The requirements of *PolygonTraits_2* are a subset of the kernel requirements. We only list the types and methods which are required and refer to the description of the kernel concept for details.

Types

PolygonTraits_2:: FT

PolygonTraits_2:: Point_2

The point type.

PolygonTraits_2:: Segment_2

The segment type.

PolygonTraits_2:: Construct_segment_2

PolygonTraits_2:: Equal_2

PolygonTraits_2:: Less_xy_2

PolygonTraits_2:: Less_yx_2

PolygonTraits_2:: Compare_x_2

PolygonTraits_2:: Compare_y_2

PolygonTraits_2:: Orientation_2

PolygonTraits_2:: Compute_area_2

Computes the signed area of the oriented triangle defined by 3 *Point_2* passed as arguments.

Creation

A default constructor and copy constructor are required.

Operations

The following functions that create instances of the above predicate object types must exist.

Equal_2 *traits.equal_2_object()*

<i>Less_xy_2</i>	<i>traits.less_xy_2_object()</i>
<i>Less_yx_2</i>	<i>traits.less_yx_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Orientation_2</i>	<i>traits.orientation_2_object()</i>
<i>Compute_area_2</i>	<i>traits.compute_area_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>

Has Models

The kernels supplied by CGAL are models of PolygonTraits_2.

CGAL::Polygon_2<PolygonTraits_2, Container> [page 726](#)

CGAL::Polygon_2<PolygonTraits_2, Container>

Definition

The class *Polygon_2<PolygonTraits_2, Container>* implements polygons. The *Polygon_2<PolygonTraits_2, Container>* is parameterised by a traits class and a container class. The latter can be any class that fulfills the requirements for an STL container. It defaults to the vector class.

```
#include <CGAL/Polygon_2.h>
```

Types

Polygon_2<PolygonTraits_2, Container>:: Traits The traits type.

Polygon_2<PolygonTraits_2, Container>:: Container

The container type.

typedef Traits::FT *FT*;

The number type, which is the *field type* of the points of the polygon.

typedef Traits::Point_2 *Point_2*;

typedef Traits::Segment_2

The point type of the polygon.

Segment_2;

The type of a segment between two points of the polygon.

The following types denote iterators that allow to traverse the vertices and edges of a polygon. Since it is questionable whether a polygon should be viewed as a circular or as a linear data structure both circulators and iterators are defined. The circulators and iterators are non-mutable.¹ The iterator category is in all cases bidirectional, except for *Vertex_iterator*, which has the same iterator category as *Container::iterator*. **N.B.** In fact all of them should have the same iterator category as *Container::iterator*. However, due to compiler problems this is currently not possible.

For vertices we define

Polygon_2<PolygonTraits_2, Container>:: Vertex_iterator

Polygon_2<PolygonTraits_2, Container>:: Vertex_circulator

Their value type is *Point_2*.

For edges we define

Polygon_2<PolygonTraits_2, Container>:: Edge_const_circulator

Polygon_2<PolygonTraits_2, Container>:: Edge_const_iterator

Their value type is *Segment_2*.

¹At least conceptually. The enforcement depends on preprocessor flags.

Creation

Polygon_2<*PolygonTraits_2*, *Container*> *pgn*(*Traits* *p_traits* = *Traits*());

Creates an empty polygon *pgn*.

template <*class InputIterator*>
Polygon_2<*PolygonTraits_2*, *Container*> *pgn*(*InputIterator* *first*,
 InputIterator *last*,
 Traits *p_traits* = *Traits*())

Introduces a polygon *pgn* with vertices from the sequence defined by the range [*first*,*last*). The value type of *InputIterator* must be *Point_2*.

Modifiers

void *pgn.set*(*Vertex_iterator* *pos*, *Point_2* *x*)

Acts as **pos* = *x*, except that that would be illegal because the iterator is not mutable.

Vertex_iterator *pgn.insert*(*Vertex_iterator* *i*, *Point_2* *q*)

Inserts the vertex *q* before *i*. The return value points to the inserted vertex.

<i>template <class InputIterator></i>	<i>pgn.insert(Vertex_iterator i, InputIterator first, InputIterator last)</i>	Inserts the vertices in the range <i>[first, last)</i> before <i>i</i> . The value type of points in the range <i>[first, last)</i> must be <i>Point_2</i> .
<i>void</i>	<i>pgn.push_back(Point_2 q)</i>	Has the same semantics as <i>p.insert(p.vertices_end(), q)</i> .
<i>void</i>	<i>pgn.erase(Vertex_iterator i)</i>	Erases the vertex pointed to by <i>i</i> .
<i>void</i>	<i>pgn.erase(Vertex_iterator first, Vertex_iterator last)</i>	Erases the vertices in the range <i>[first, last)</i> .
<i>void</i>	<i>pgn.clear()</i>	Erases all vertices.
<i>void</i>	<i>pgn.reverse_orientation()</i>	Reverses the orientation of the polygon. The vertex pointed to by <i>p.vertices_begin()</i> remains the same.

Access Functions

The following methods of the class return circulators and iterators that allow to traverse the vertices and edges.

<i>Vertex_iterator</i>	<i>pgn.vertices_begin()</i>	Returns a constant iterator that allows to traverse the vertices of the polygon <i>p</i> .
<i>Vertex_iterator</i>	<i>pgn.vertices_end()</i>	Returns the corresponding past-the-end iterator.
<i>Vertex_circulator</i>	<i>pgn.vertices_circulator()</i>	Returns a mutable circulator that allows to traverse the vertices of the polygon <i>p</i> .
<i>Edge_const_iterator</i>	<i>pgn.edges_begin()</i>	Returns a non-mutable iterator that allows to traverse the edges of the polygon <i>p</i> .
<i>Edge_const_iterator</i>	<i>pgn.edges_end()</i>	Returns the corresponding past-the-end iterator.
<i>Edge_const_circulator</i>	<i>pgn.edges_circulator()</i>	Returns a non-mutable circulator that allows to traverse the edges of the polygon <i>p</i> .

Predicates

<i>bool</i>	<i>pgn.is_simple()</i>	Returns whether <i>p</i> is a simple polygon.
<i>bool</i>	<i>pgn.is_convex()</i>	Returns whether <i>p</i> is convex.
<i>Orientation</i>	<i>pgn.orientation()</i>	Returns the orientation of <i>pgn</i> . If the number of vertices <i>p.size()</i> < 3 then <i>COLLINEAR</i> is returned. <i>Precondition: p.is_simple().</i>
<i>Oriented_side</i>	<i>pgn.oriented_side(Point_2 q)</i>	Returns <i>POSITIVE_SIDE</i> , or <i>NEGATIVE_SIDE</i> , or <i>ON_ORIENTED_BOUNDARY</i> , depending on where point <i>q</i> is. <i>Precondition: p.is_simple().</i>
<i>Bounded_side</i>	<i>pgn.bounded_side(Point_2 q)</i>	Returns the symbolic constant <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> or <i>ON_UNBOUNDED_SIDE</i> , depending on where point <i>q</i> is. <i>Precondition: p.is_simple().</i>
<i>Bbox_2</i>	<i>pgn.bbox()</i>	Returns the smallest bounding box containing <i>pgn</i> .
<i>Traits::FT</i>	<i>pgn.area()</i>	Returns the signed area of the polygon <i>pgn</i> . This means that the area is positive for counter clockwise polygons and negative for clockwise polygons.
<i>Vertex_iterator</i>	<i>pgn.left_vertex()</i>	Returns the leftmost vertex of the polygon <i>p</i> with the smallest y-coordinate.
<i>Vertex_iterator</i>	<i>pgn.right_vertex()</i>	Returns the rightmost vertex of the polygon <i>p</i> with the largest y-coordinate.
<i>Vertex_iterator</i>	<i>pgn.top_vertex()</i>	Returns topmost vertex of the polygon <i>p</i> with the largest x-coordinate.
<i>Vertex_iterator</i>	<i>pgn.bottom_vertex()</i>	Returns the bottommost vertex of the polygon <i>p</i> with the smallest x-coordinate.

For convenience we provide the following boolean functions:

<i>bool</i>	<i>pgn.is_counterclockwise_oriented()</i>
<i>bool</i>	<i>pgn.is_clockwise_oriented()</i>
<i>bool</i>	<i>pgn.is_collinear_oriented()</i>
<i>bool</i>	<i>pgn.has_on_positive_side(Point_2 q)</i>
<i>bool</i>	<i>pgn.has_on_negative_side(Point_2 q)</i>
<i>bool</i>	<i>pgn.has_on_boundary(Point_2 q)</i>

bool *pgn.has_on_bounded_side(Point_2 q)*
bool *pgn.has_on_unbounded_side(Point_2 q)*

Random access methods

These methods are only available for random access containers.

Point_2 *pgn.vertex(int i)* Returns a (const) reference to the *i*-th vertex.

Point_2 *pgn[int i]* Returns a (const) reference to the *i*-th vertex.

Segment_2 *pgn.edge(int i)* Returns a const reference to the *i*-th edge.

Miscellaneous

int *pgn.size()* Returns the number of vertices of the polygon *pgn*.

bool *pgn.is_empty()* Returns *p.size() == 0*.

Container *pgn.container()* Returns a const reference to the sequence of vertices of the polygon *pgn*.

Globally defined operators

template <class Traits, class Container1, class Container2>

bool *Polygon_2<Traits,Container1> p1 == Polygon_2<Traits,Container2> p2*

Test for equality: two polygons are equal iff there exists a cyclic permutation of the vertices of *p2* such that they are equal to the vertices of *p1*. Note that the template argument *Container* of *p1* and *p2* may be different.

template <class Traits, class Container1, class Container2>

bool *Polygon_2<Traits,Container1> p1 != Polygon_2<Traits,Container2> p2*

Test for inequality.

template <class Transformation, class Traits, class Container>

Polygon_2<Traits,Container>

transform(Transformation t, Polygon_2<Traits,Container> p)

Returns the image of the polygon *p* under the transformation *t*.

Implementation

The methods *is_simple*, *is_convex*, *orientation*, *oriented_side*, *bounded_side*, *bbox*, *area*, *left_vertex*, *right_vertex*, *top_vertex* and *bottom_vertex* are all implemented using the algorithms on sequences of 2D points. See the corresponding global functions for information about which algorithms were used and what complexity they have.

Example

The following code fragment creates a polygon and checks if it is convex.

```
// file: examples/Polygon/Polygon.C

#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

typedef CGAL::Cartesian<double> K;
typedef K::Point_2 Point;
typedef CGAL::Polygon_2<K> Polygon;
using std::cout; using std::endl;

int main()
{
    Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6) };
    Polygon pgn(points, points+4);

    // check if the polygon is simple.
    cout << "The polygon is " <<
        (pgn.is_simple() ? "" : "not ") << "simple." << endl;

    // check if the polygon is convex
    cout << "The polygon is " <<
        (pgn.is_convex() ? "" : "not ") << "convex." << endl;

    return 0;
}
```

CGAL::polygon_area_2

Definition

The function *polygon_area_2* computes the signed area of a polygon.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
typename Traits::FT      polygon_area_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Computes the signed area of the polygon defined by the range of points *first* ... *last*. The sign is positive for counterclockwise polygons, negative for clockwise polygons. If the polygon is not simple, the area is not well defined.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
 - *Compute_area_2* : Computes the signed area of the oriented triangle defined by 3 *Point_2* passed as arguments.
 - *FT*
 - *compute_area_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

CGAL::right_vertex_2

Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator      right_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the rightmost point from the range $[first, last)$. In case of a tie, the point with the largest y-coordinate is taken.

Requirements

1. *Traits* is a model of the concept `PolygonTraits_2`. In fact, only the members `Less_xy_2` and `less_xy_2_object` are used.
2. `ForwardIterator::value_type` should be `Traits::Point_2`,

CGAL::top_vertex_2

Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator top_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the topmost point from the range *[first,last)*. In case of a tie, the point with the largest *x*-coordinate is taken.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. In fact, only the members *Less_yx_2* and *less_yx_2_object* are used.
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

Chapter 9

2D Polygon Partitioning

Susan Hert

Contents

9.1 Introduction	735
9.2 Monotone Partitioning	735
9.3 Convex Partitioning	736

9.1 Introduction

A *partition* of a polygon P is a set of polygons such that the interiors of the polygons do not intersect and the union of the polygons is equal to the interior of the original polygon P . This chapter describes functions for partitioning planar polygons into two types of subpolygons — y -monotone polygons and convex polygons. The partitions are produced without introducing new (Steiner) vertices.

All the partitioning functions present the same interface to the user. That is, the user provides a pair of input iterators, *first* and *beyond*, an output iterator *result*, and a traits class *traits*. The points in the range $[first, beyond)$ are assumed to define a simple polygon whose vertices are in counterclockwise order. The computed partition polygons, whose vertices are also oriented counterclockwise, are written to the sequence starting at position *result* and the past-the-end iterator for the resulting sequence of polygons is returned. The traits classes for the functions specify the types of the input points and output polygons as well as a few other types and function objects that are required by the various algorithms.

9.2 Monotone Partitioning

A *y-monotone polygon* is a polygon whose vertices v_1, \dots, v_n can be divided into two chains v_1, \dots, v_k and v_k, \dots, v_n, v_1 , such that any horizontal line intersects either chain at most once. For producing a y -monotone partition of a given polygon, the sweep-line algorithm presented in [dBvKOS97] is implemented by the function `y_monotone_partition_2`. This algorithm runs in $O(n \log n)$ time and requires $O(n)$ space. This algorithm does not guarantee a bound on the number of polygons produced with respect to the optimal number.

For checking the validity of the partitions produced by `y_monotone_partition_2`, we provide a function `is_y_monotone_2`, which determines if a sequence of points in 2D defines a y -monotone polygon or not. For examples of the use of these functions, see the corresponding reference pages.

Figure 9.1: Examples of an optimal convex partition (left) and an approximately optimal convex partition (right).

9.3 Convex Partitioning

Three functions are provided for producing convex partitions of polygons. One produces a partition that is optimal in the number of pieces. The other two functions produce approximately optimal convex partitions. Both these functions produce convex decompositions by first decomposing the polygon into simpler polygons; the first uses a triangulation and the second a monotone partition. These two functions both guarantee that they will produce no more than four times the optimal number of convex pieces but they differ in their runtime complexities. Though the triangulation-based approximation algorithm often results in fewer convex pieces, this is not always the case.

An optimal convex partition can be produced using the function *optimal_convex_partition_2*. This function provides an implementation of Greene’s dynamic programming algorithm for optimal partitioning [Gre83]. This algorithm requires $O(n^4)$ time and $O(n^3)$ space in the worst case.

The function *approx_convex_partition_2* implements the simple approximation algorithm of Hertel and Mehlhorn [HM83] that produces a convex partitioning of a polygon from a triangulation by throwing out unnecessary triangulation edges. The triangulation used in this function is one produced by the 2-dimensional constrained triangulation package of CGAL. For a given triangulation, this convex partitioning algorithm requires $O(n)$ time and space to construct a decomposition into no more than four times the optimal number of convex pieces.

The sweep-line approximation algorithm of Greene [Gre83], which, given a monotone partition of a polygon, produces a convex partition in $O(n \log n)$ time and $O(n)$ space, is implemented by the function *greene_approx_convex_partition_2*. The function *y_monotone_partition_2* described in Section 9.2 is used to produce the monotone partition. This algorithm provides the same worst-case approximation guarantee as the algorithm of Hertel and Mehlhorn implemented with *approx_convex_partition_2* but can sometimes produce better results (*i.e.*, convex partitions with fewer pieces).

Examples of the uses of all of these functions are provided with the corresponding reference pages.

2D Polygon Partitioning

Reference Manual

Susan Hert

A *partition* of a polygon is a set of polygons such that the interiors of the polygons do not intersect and the union of the polygons is equal to the interior of the original polygon. Functions are available for partitioning planar polygons into two types of subpolygons — y-monotone polygons and convex polygons.

The function that produces a y-monotone partitioning is based on the algorithm presented in [dBvKOS97] which requires $O(n \log n)$ time and $O(n)$ space for a polygon with n vertices and guarantees nothing about the number of polygons produced with respect to the optimal number. Three functions are provided for producing convex partitionings. Two of these functions produce approximately optimal partitions and one results in an optimal partition, where “optimal” is defined in terms of the number of partition polygons. The two functions that implement approximation algorithms are guaranteed to produce no more than four times the optimal number of convex pieces. The optimal partitioning function provides an implementation of Greene’s dynamic programming algorithm [Gre83], which requires $O(n^4)$ time and $O(n^3)$ space to produce a convex partitioning. One of the approximation algorithms is also due to Greene [Gre83] and requires $O(n \log n)$ time and $O(n)$ space to produce a convex partitioning given a y-monotone partitioning. The other approximation algorithm is a result of Hertel and Mehlhorn [HM83], which requires $O(n)$ time and space to produce a convex partitioning from a triangulation of a polygon. Each of the partitioning functions uses a traits class to supply the primitive types and predicates used by the algorithms.

Assertions

The assertion flags for this package use *PARTITION* in their names (e.g., *CGAL_PARTITION_NO_POSTCONDITIONS*). The precondition checks for the planar polygon partitioning functions are: counterclockwise ordering of the input vertices and simplicity of the polygon these vertices represent. The postcondition checks are: simplicity, counterclockwise orientation, and convexity (or y-monotonicity) of the partition polygons and validity of the partition (i.e., the partition polygons are nonoverlapping and the union of these polygons is the same as the original polygon).

CGAL::approx_convex_partition_2

Definition

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is no more than four times the minimal number.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      approx_convex_partition_2( InputIterator first,
                                              InputIterator beyond,
                                              OutputIterator result,
                                              Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range $[first, beyond)$ into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

Precondition: The points in the range $[first, beyond)$ define a simple counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept `PartitionTraits_2` and, for the purposes of checking the postcondition that the partition produced is valid, it should also be a model of the concept `ConvexPartitionIsValidTraits_2`.
2. `OutputIterator::value_type` should be `Traits::Polygon_2`.
3. `InputIterator::value_type` should be `Traits::Point_2`, which should also be the type of the points stored in an object of type `Traits::Polygon_2`.
4. Points in the range $[first, beyond)$ must define a simple polygon whose vertices are oriented counterclockwise.

The default traits class `Default_traits` is `Partition_traits_2`, with the representation type determined by `InputIterator1::value_type`.

[CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid>](#) page 767
[CGAL::y_monotone_partition_2](#) page 772

Implementation

This function implements the algorithm of Hertel and Mehlhorn [HM83] and is based on the class `CGAL::Constrained_triangulation_2`. Given a triangulation of the polygon, the function requires $O(n)$ time and space for a polygon with n vertices.

Example

The following program computes an approximately optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*.

```
// file: examples/Partition_2/approx_convex_partition.C

CGAL::convex_partition_is_valid_2

Definition

Function that determines if a given set of polygons represents a valid convex partitioning for a given sequence of points that represent a simple, counterclockwise-oriented polygon. A convex partition is valid if the polygons do not overlap, the union of the polygons is the same as the original polygon given by the sequence of points, and if each partition polygon is convex.

```
#include <CGAL/partition_is_valid_2.h>
```

```
template<class InputIterator, class ForwardIterator, class Traits>
bool      convex_partition_is_valid_2( InputIterator point_first,
                                      InputIterator point_beyond,
                                      ForwardIterator poly_first,
                                      ForwardIterator poly_beyond,
                                      Traits traits = Default_traits)
```

determines if the polygons in the range `[poly_first, poly_beyond)` define a valid convex partition of the polygon defined by the points in the range `[point_first, point_beyond)`. The function returns *true* iff the partition is valid and otherwise returns *false*.

Precondition: The points in the range `[point_first, point_beyond)` define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept `ConvexPartitionIsValidTraits_2`.
2. `InputIterator::value_type` should be `Traits::Point_2`, which should also be the type of the points stored in an object of type `Traits::Polygon_2`.
3. `ForwardIterator::value_type` should be `Traits::Polygon_2`.

The default traits class `Default_traits` is `Partition_traits_2`, with the representation type determined by `InputIterator::value_type`.

`CGAL::optimal_convex_partition_2` page 756
`CGAL::partition_is_valid_2` page 761
`CGAL::is_convex_2`

Implementation

This function calls *partition_is_valid_2* using the function object *Is_convex_2* to determine the convexity of each partition polygon. Thus the time required by this function is $O(n \log n + e \log e)$ where n is the total number of vertices in the partition polygons and e the total number of edges.

Example

See the example presented with the function *approx_convex_partition_2* for an illustration of the use of this function.

_____ *advanced* _____

ConvexPartitionIsValidTraits_2

Definition

Requirements of a traits class used by *convex_partition_is_valid_2* for testing the validity of a convex partition of a polygon.

Types

All types required by the concept `PartitionIsValidTraits_2` are required except the function object type *Is_valid*. The following type is required instead:

ConvexPartitionIsValidTraits_2::Is_convex_2 Model of the concept `PolygonIsValid` that tests if a sequence of points is convex or not.

Creation

Only a copy constructor is required.

ConvexPartitionIsValidTraits_2 traits(& tr);

Operations

The following function that creates an instance of the above predicate object type must exist instead of the function *is_valid_object* required by `PartitionIsValidTraits_2`.

Is_convex_2 traits.is_convex_2_object(t)

Has Models

CGAL::Partition_traits_2<R> page 769

CGAL::greene_approx_convex_partition_2

Definition

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is no more than four times the minimal number.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      greene_approx_convex_partition_2( InputIterator first,
                                                    InputIterator beyond,
                                                    OutputIterator result,
                                                    Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range $[first, beyond)$ into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

Precondition: The points in the range $[first, beyond)$ define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concepts *PartitionTraits_2* and *YMonotonePartitionTraits_2*. For the purpose of checking the validity of the y-monotone partition produced as a preprocessing step for the convex partitioning, it must also be a model of *YMonotonePartitionIsValidTraits_2*. For the purpose of checking the postcondition that the convex partition is valid, *Traits* must also be a model of *ConvexPartitionIsValidTraits_2*.
2. *OutputIterator::value_type* is equivalent to *Traits::Polygon_2*.
3. *InputIterator::value_type* is equivalent to *Traits::Point_2*, which should also be equivalent to the type of the points stored in an object of type *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::optimal_convex_partition_2 [page 756](#)
CGAL::partition_is_valid_2 [page 761](#)
CGAL::y_monotone_partition_2 [page 772](#)

Implementation

This function implements the approximation algorithm of Greene [Gre83] and requires $O(n \log n)$ time and $O(n)$ space to produce a convex partitioning given a y -monotone partitioning of a polygon with n vertices. The function `y_monotone_partition_2` is used to produce the monotone partition.

Example

The following program computes an approximately optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list `partition_polys`.

```
// file: examples/Partition_2/greene_approx_convex_partition_2.C

#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K> Traits;
typedef Traits::Point_2 Point_2;
typedef Traits::Polygon_2 Polygon_2;
typedef Polygon_2::Vertex_iterator Vertex_iterator;
typedef std::list<Polygon_2> Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2< Point_2, Creator > Point_generator;

void make_polygon(Polygon_2& polygon)
{
    polygon.push_back(Point_2(391, 374));
    polygon.push_back(Point_2(240, 431));
    polygon.push_back(Point_2(252, 340));
    polygon.push_back(Point_2(374, 320));
    polygon.push_back(Point_2(289, 214));
    polygon.push_back(Point_2(134, 390));
    polygon.push_back(Point_2( 68, 186));
    polygon.push_back(Point_2(154, 259));
    polygon.push_back(Point_2(161, 107));
    polygon.push_back(Point_2(435, 108));
    polygon.push_back(Point_2(208, 148));
    polygon.push_back(Point_2(295, 160));
    polygon.push_back(Point_2(421, 212));
    polygon.push_back(Point_2(441, 303));
}

int main()
{
    Polygon_2    polygon;
```

```

Polygon_list partition_polys;
Traits        partition_traits;

/*
   CGAL::random_polygon_2(50, std::back_inserter(polygon),
                        Point_generator(100));
*/
make_polygon(polygon);
CGAL::greene_approx_convex_partition_2(polygon.vertices_begin(),
                                       polygon.vertices_end(),
                                       std::back_inserter(partition_polys),
                                       partition_traits);
assert(CGAL::convex_partition_is_valid_2(polygon.vertices_begin(),
                                       polygon.vertices_end(),
                                       partition_polys.begin(),
                                       partition_polys.end(),
                                       partition_traits));

return 0;
}

```

CGAL::is_y_monotone_2

Definition

Function for testing the y-monotonicity of a sequence of points.

```
#include <CGAL/is_y_monotone_2.h>
```

```
template<class InputIterator, class Traits>
bool is_y_monotone_2( InputIterator first, InputIterator beyond, Traits traits)
```

Determines if the sequence of points in the range *[first, beyond)* define a y-monotone polygon or not. If so, the function returns *true*, otherwise it returns *false*.

Requirements

1. *Traits* is a model of the concept *IsYMonotoneTraits_2*.
2. *InputIterator::value_type* should be *Traits::Point_2*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

See Also

CGAL::Is_y_monotone_2<Traits> page [755](#)
CGAL::y_monotone_partition_2 page [772](#)
CGAL::y_monotone_partition_is_valid_2 page [775](#)

Implementation

This function requires $O(n)$ time for a polygon with n vertices.

Example

The following program computes a y-monotone partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*. It then asserts that each of the partition polygons is, in fact, a y-monotone polygon and that the partition is valid. (Note that the assertions are superfluous unless the postcondition checking done by *y_monotone_partition_2* has been turned off during compilation.)

```
// file: examples/Partition_2/y_monotone_partition_2.C

#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
```

```

#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K> Traits;
typedef Traits::Point_2 Point_2;
typedef Traits::Polygon_2 Polygon_2;
typedef std::list<Polygon_2> Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator> Point_generator;

void make_polygon(Polygon_2& polygon)
{
    polygon.push_back(Point_2(391, 374));
    polygon.push_back(Point_2(240, 431));
    polygon.push_back(Point_2(252, 340));
    polygon.push_back(Point_2(374, 320));
    polygon.push_back(Point_2(289, 214));
    polygon.push_back(Point_2(134, 390));
    polygon.push_back(Point_2( 68, 186));
    polygon.push_back(Point_2(154, 259));
    polygon.push_back(Point_2(161, 107));
    polygon.push_back(Point_2(435, 108));
    polygon.push_back(Point_2(208, 148));
    polygon.push_back(Point_2(295, 160));
    polygon.push_back(Point_2(421, 212));
    polygon.push_back(Point_2(441, 303));
}

int main( )
{
    Polygon_2    polygon;
    Polygon_list partition_polys;

    /*
    CGAL::random_polygon_2(50, std::back_inserter(polygon),
                          Point_generator(100));
    */

    make_polygon(polygon);
    CGAL::y_monotone_partition_2(polygon.vertices_begin(),
                                polygon.vertices_end(),
                                std::back_inserter(partition_polys));

    std::list<Polygon_2>::const_iterator poly_it;
    for (poly_it = partition_polys.begin(); poly_it != partition_polys.end();
         poly_it++)
    {
        assert(CGAL::is_y_monotone_2((*poly_it).vertices_begin(),
                                     (*poly_it).vertices_end()));
    }
}

```

```
    assert(CGAL::partition_is_valid_2(polygon.vertices_begin(),
                                      polygon.vertices_end(),
                                      partition_polys.begin(),
                                      partition_polys.end()));

    return 0;
}
```

IsYMonotoneTraits_2

Definition

Requirements of a traits class to be used with the function *is_y_monotone_2* that tests whether a sequence of 2D points defines a y-monotone polygon or not.

Types

The following two types are required:

IsYMonotoneTraits_2:: Point_2

The point type of the polygon vertices.

IsYMonotoneTraits_2:: Less_yx_2

Predicate object type that compares *Point_2*s lexicographically. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote x and y coordinate of point p resp.

Creation

Only a copy constructor is required.

IsYMonotoneTraits_2 traits(& tr);

Operations

The following function that creates an instance of the above predicate object type must exist:

Less_yx_2 traits.less_yx_2_object()

Has Models

CGAL::Is_convex_2<Traits>

Definition

Function object class for testing if a sequence of points represents a convex polygon or not.

`#include <CGAL/polygon_function_objects.h>`

Is Model for the Concepts

PolygonIsValid page [771](#)

Creation

`Is_convex_2<Traits> f(Traits t);` *Traits* satisfies the requiriements of the function `is_convex_2`

Operations

`template<class InputIterator>`
`bool f(InputIterator first, InputIterator beyond)`

returns *true* iff the points of type *Triats::Point_2* in the range `[first,beyond)` define a convex polygon.

See Also

`CGAL::convex_partition_is_valid_2` page [743](#)

Implementation

This test requires $O(n)$ time for a polygon with n vertices.

CGAL::Is_vacuously_valid<Traits>

Definition

Function object class that indicates all sequences of points are valid.

```
#include <CGAL/polygon_function_objects.h>
```

Is Model for the Concepts

PolygonIsValid page [771](#)

Creation

```
Is_vacuously_valid<Traits> f( Traits t);
```

Operations

```
template<class InputIterator>
bool      f( InputIterator first, InputIterator beyond)      returns true.
```

See Also

Implementation

This test requires $O(1)$ time.

CGAL::Is_y_monotone_2<Traits>

Definition

Function object class that tests whether a sequence of points represents a y-monotone polygon or not.

#include <CGAL/polygon_function_objects.h>

Is Model for the Concepts

PolygonIsValid page [771](#)

Creation

Is_y_monotone_2<Traits> f(Traits t); *Traits* is a model of the concept IsYMonotoneTraits_2

Operations

template<class InputIterator>
bool f(InputIterator first, InputIterator beyond)

returns *true* iff the points of type *Traits::Point_2* in the range *[first,beyond)* define a y-monotone polygon.

See Also

Implementation

This test requires $O(n)$ time for a polygon with n vertices.

CGAL::optimal_convex_partition_2

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is minimal.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      optimal_convex_partition_2( InputIterator first,
                                                InputIterator beyond,
                                                OutputIterator result,
                                                Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range $[first, beyond)$ into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

Precondition: The points in the range $[first, beyond)$ define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept `OptimalConvexPartitionTraits_2`. For the purposes of checking the post-condition that the partition is valid, *Traits* should also be a model of `ConvexPartitionIsValidTraits_2`.
2. `OutputIterator::value_type` should be `Traits::Polygon_2`.
3. `InputIterator::value_type` should be `Traits::Point_2`, which should also be the type of the points stored in an object of type `Traits::Polygon_2`.

The default traits class `Default_traits` is `Partition_traits_2`, with the representation type determined by `InputIterator::value_type`.

`CGAL::partition_is_valid_2` page [761](#)
`CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid>` page [767](#)

Implementation

This function implements the dynamic programming algorithm of Greene [[Gre83](#)], which requires $O(n^4)$ time and $O(n^3)$ space to produce a partitioning of a polygon with n vertices.

Example

The following program computes an optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*. It then asserts that the partition produced is valid. The traits class used for testing the validity is derived from the traits class used to produce the partition with the function object class *CGAL::Is_convex_2* used to define the required *Is_valid* type. (Note that this assertion is superfluous unless the postcondition checking for *optimal_convex_partition_2* has been turned off.)

OptimalConvexPartitionTraits_2

Definition

Requirements of a traits class to be used with the function *optimal_convex_partition_2* that computes an optimal convex partition of a polygon.

Generalizes

PartitionTraits_2 page 765

Types

In addition to the types listed with the concept PartitionTraits_2, the following types are required:

OptimalConvexPartitionTraits_2:: Segment_2 A segment type

OptimalConvexPartitionTraits_2:: Ray_2 A ray type

OptimalConvexPartitionTraits_2:: Object_2 A general object type that can be either a point or a segment

OptimalConvexPartitionTraits_2:: Construct_segment_2

Function object type that provides *Segment_2* *operator()(Point_2 p, Point_2 q)*, which constructs and returns the segment defined by the points *p* and *q*.

OptimalConvexPartitionTraits_2:: Construct_ray_2

Function object type that provides *Ray_2* *operator()(Point_2 p, Point_2 q)*, which constructs and returns the ray from point *p* through point *q*.

OptimalConvexPartitionTraits_2:: Collinear_are_ordered_along_line_2

Predicate object type that determines orderings of *Point_2*s on a line. Must provide *bool operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *true*, iff *q* lies between *p* and *r* and *p*, *q*, and *r* satisfy the precondition that they are collinear.

OptimalConvexPartitionTraits_2:: Are_strictly_ordered_along_line_2

Predicate object type that determines orderings of *Point_2*s. Must provide *bool operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *true*, iff the three points are collinear and *q* lies strictly between *p* and *r*. Note that *false* should be returned if *q==p* or *q==r*.

<i>OptimalConvexPartitionTraits_2:: Intersect_2</i>	Function object type that provides <i>Object_2 operator()(Segment_2 s1, Segment_2 s2)</i> that returns the intersection of two segments (which may be either a segment or a point).
<i>OptimalConvexPartitionTraits_2:: Assign_2</i>	Function object type that provides <i>bool operator()(Segment_2 s1, Object_2 o)</i> that returns <i>true</i> if <i>o</i> is a segment and assigns the value of <i>o</i> to <i>s1</i> ; returns <i>false</i> otherwise.

Creation

Only a copy constructor is required.

OptimalConvexPartitionTraits_2 traits(& tr);

Operations

In addition to the functions required by *PartitionTraits_2*, the following functions that create instances of the above function object types must exist:

<i>Collinear_are_ordered_along_line_2</i>	<i>traits.collinear_are_ordered_along_line_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_ray_2</i>	<i>traits.construct_ray_2_object()</i>
<i>Are_strictly_ordered_along_line_2</i>	<i>traits.are_strictly_ordered_along_line_2_object()</i>

CGAL::partition_is_valid_2

Definition

Function that determines if a given set of polygons represents a valid partition for a given sequence of points that define a simple, counterclockwise-oriented polygon. A valid partition is one in which the polygons are nonoverlapping and the union of the polygons is the same as the original polygon.

```
#include <CGAL/partition_is_valid_2.h>
```

```
template<class InputIterator, class ForwardIterator, class Traits>
bool partition_is_valid_2( InputIterator point_first,
                          InputIterator point_beyond,
                          ForwardIterator poly_first,
                          ForwardIterator poly_beyond,
                          Traits traits = Default_traits)
```

returns *true* iff the polygons in the range $[poly_first, poly_beyond)$ define a valid partition of the polygon defined by the points in the range $[point_first, point_beyond)$ and *false* otherwise. Each polygon must also satisfy the property tested by *Traits::Is_valid()*.

Precondition: Points in the range $[point_first, point_beyond)$ define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *PartitionIsValidTraits_2* and the concept defining the requirements for the validity test implemented by *Traits::Is_valid()*.
2. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.
3. *ForwardIterator::value_type* should be *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::Partition_is_valid_traits_2<*Traits*, *PolygonIsValid*> page 767
CGAL::y_monotone_partition_2 page 772
CGAL::is_convex_2

Implementation

This function requires $O(n \log n + e \log e + \sum_{i=1}^p m_i)$ where n is the total number of vertices of the p partition polygons, e is the total number of edges of the partition polygons and m_i is the time required by *Traits::Is_valid()* to test if partition polygon p_i is valid.

Example

See the example presented with the function *optimal_convex_partition_2* for an illustration of the use of this function.

_____ *advanced* _____

PartitionIsValidTraits_2

Definition

Requirements of a traits class that is used by *partition_is_valid_2*, *convex_partition_is_valid_2*, and *y_monotone_partition_is_valid_2* for testing if a given set of polygons are nonoverlapping and if their union is a polygon that is the same as a polygon represented by a given sequence of points. Note that the traits class for *partition_is_valid_2* may have to satisfy additional requirements if each partition polygon is to be tested for having a particular property; see, for example, the descriptions of the function *is_convex_2* and the concept *YMonotonePartitionTraits_2* for the additional requirements for testing for convexity and y-monotonicity, respectively.

Types

<i>PartitionIsValidTraits_2:: Point_2</i>	The point type on which the partitioning algorithm operates.
<i>PartitionIsValidTraits_2:: Polygon_2</i>	The polygon type created by the partitioning function. This type should provide a nested type <i>Vertex_const_iterator</i> that is the type of the non-mutable iterator over the polygon vertices.
<i>PartitionIsValidTraits_2:: Is_valid</i>	A model of the concept <i>PolygonIsValid</i>
<i>PartitionIsValidTraits_2:: Less_xy_2</i>	Predicate object type that compares <i>Point_2</i> s lexicographically. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote the x and y coordinates of point p , respectively.
<i>PartitionIsValidTraits_2:: Left_turn_2</i>	Predicate object type that provides <i>bool operator()(Point_2 p, Point_2 q, Point_2 r)</i> , which returns <i>true</i> iff r lies to the left of the oriented line through p and q .
<i>PartitionIsValidTraits_2:: Orientation_2</i>	Predicate object type that provides <i>CGAL::Orientation operator()(Point_2 p, Point_2 q, Point_2 r)</i> that returns <i>CGAL::LEFT_TURN</i> , if r lies to the left of the oriented line l defined by p and q , returns <i>CGAL::RIGHT_TURN</i> if r lies to the right of l , and returns <i>CGAL::COLLINEAR</i> if r lies on l .

Creation

Only a copy constructor is required.

```
PartitionIsValidTraits_2 traits( & tr);
```

Operations

The following functions that create instances of the above predicate object types must exist.

Orientation_2 *traits.is_valid_object()*

Less_xy_2 *traits.less_xy_2_object()*

Left_turn_2 *traits.left_turn_2_object()*

Orientation_2 *traits.orientation_2_object()*

PartitionTraits_2

Definition

The polygon partitioning functions are each parameterized by a traits class that defines the primitives used in the algorithms. Many requirements are common to all traits classes. The concept `PartitionTraits_2` defines this common set of requirements.

Types

<code>PartitionTraits_2:: Point_2</code>	The point type on which the partitioning algorithm operates.
<code>PartitionTraits_2:: Polygon_2</code>	The polygon type to be created by the partitioning algorithm. For testing the validity postcondition of the partition, this type should provide a nested type <i>Vertex_const_iterator</i> that is the type of the iterator over the polygon vertices and member functions <i>Vertex_const_iterator vertices_begin()</i> and <i>Vertex_const_iterator vertices_end()</i> .
<code>PartitionTraits_2:: Less_xy_2</code>	Predicate object type that compares <i>Point_2</i> s lexicographically. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote the x and y coordinates of point p , respectively.
<code>PartitionTraits_2:: Less_yx_2</code>	Same as <i>Less_xy_2</i> with the roles of x and y interchanged.
<code>PartitionTraits_2:: Left_turn_2</code>	Predicate object type that provides <i>bool operator()(Point_2 p, Point_2 q, Point_2 r)</i> , which returns <i>true</i> iff r lies to the left of the oriented line through p and q .
<code>PartitionTraits_2:: Orientation_2</code>	Predicate object type that provides <i>CGAL::Orientation operator()(Point_2 p, Point_2 q, Point_2 r)</i> that returns <i>CGAL::LEFT_TURN</i> , if r lies to the left of the oriented line l defined by p and q , returns <i>CGAL::RIGHT_TURN</i> if r lies to the right of l , and returns <i>CGAL::COLLINEAR</i> if r lies on l .
<code>PartitionTraits_2:: Compare_y_2</code>	Predicate object type that provides <i>CGAL::Comparison_result operator()(Point_2 p, Point_2 q)</i> to compare the y values of two points. The operator must return <i>CGAL::SMALLER</i> if $p_y < q_y$, <i>CGAL::LARGER</i> if $p_y > q_y$ and <i>CGAL::EQUAL</i> if $p_y = q_y$.
<code>PartitionTraits_2:: Compare_x_2</code>	The same as <i>Compare_y_2</i> , except that x coordinates are compared instead of y .

Creation

A copy constructor and default constructor are required.

```
PartitionTraits_2 traits;
```

```
PartitionTraits_2 traits( & tr);
```

Operations

The following functions that create instances of the above predicate object types must exist.

```
Less_yx_2          traits.less_yx_2_object()
```

```
Less_xy_2          traits.less_xy_2_object()
```

```
Left_turn_2       traits.left_turn_2_object()
```

```
Orientation_2     traits.orientation_2_object()
```

```
Compare_y_2       traits.compare_y_2_object()
```

```
Compare_x_2       traits.compare_x_2_object()
```

CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid>

Definition

Class that derives a traits class for *partition_is_valid_2* from a given traits class by defining the validity testing function object in terms of a supplied template parameter.

```
#include <CGAL/Partition_is_valid_traits_2.h>
```

Inherits From

Traits

Is Model for the Concepts

PartitionIsValidTraits_2

Types

```
typedef PolygonIsValid      Is_valid;
typedef Traits::Point_2     Point_2;
typedef Traits::Polygon_2   Polygon_2;
typedef Traits::Less_xy_2   Less_xy_2;
typedef Traits::Left_turn_2 Left_turn_2;
typedef Traits::Orientation_2 Orientation_2;
```

Operations

The constructors and member functions for creating instances of the above types are inherited from *Traits*. In addition, the following member function is defined:

<i>Is_valid</i>	<i>traits.is_valid_object(Traits traits)</i>
-----------------	-----------------------------------------------

function returning an instance of *Is_valid*

PolygonIsValid

Definition

Function object that determines if a sequence of points represents a valid partition polygon or not, where “valid” can assume any of several meanings (*e.g.*, convex or *y*-monotone).

Creation

PolygonIsValid *f*(*Traits* *t*);

Traits is a model of the concept required by the function that checks for validity of the polygon.

Operations

```
template<class InputIterator>
bool f( InputIterator first, InputIterator beyond)
```

returns *true* iff the points of type *Traits::Point_2* in the range [*first*,*beyond*) define a valid polygon.

Has Models

CGAL::y_monotone_partition_2

Definition

Function that produces a set of y-monotone polygons that represent a partitioning of a polygon defined on a sequence of points.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      y_monotone_partition_2( InputIterator first,
                                           InputIterator beyond,
                                           OutputIterator result,
                                           Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range $[first, beyond)$ into y-monotone polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

Precondition: The points in the range $[first, beyond)$ define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *YMonotonePartitionTraits_2* and, for the purposes of checking the post-condition that the partition is valid, it should also be a model of *YMonotonePartitionIsValidTraits_2*.
2. *OutputIterator::value_type* should be *Traits::Polygon_2*.
3. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

 CGAL::optimal_convex_partition_2 page [756](#)
 CGAL::partition_is_valid_2 page [761](#)
 CGAL::y_monotone_partition_is_valid_2 page [775](#)

Implementation

This function implements the algorithm presented by de Berg *et al.* [[dBvKOS97](#)] which requires $O(n \log n)$ time and $O(n)$ space for a polygon with n vertices.

Example

The following program computes a y-monotone partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*. It then asserts that each partition polygon produced is, in fact, y-monotone and that the partition is valid. (Note that these assertions are superfluous unless the postcondition checking for *y_monotone_partition_2* has been turned off.)

```

return 0;
}

```

CGAL::y_monotone_partition_is_valid_2

Definition

Function that determines if a given set of polygons represents a valid y-monotone partitioning for a given sequence of points that define a simple, counterclockwise-oriented polygon. A valid partition is one in which the polygons are nonoverlapping and the union of the polygons is the same as the original polygon and each polygon is y-monotone

```
#include <CGAL/partition_is_valid_2.h>
```

```
template<class InputIterator, class ForwardIterator, class Traits>
bool y_monotone_partition_is_valid_2( InputIterator point_first,
                                     InputIterator point_beyond,
                                     ForwardIterator poly_first,
                                     ForwardIterator poly_beyond,
                                     Traits traits = Default_traits)
```

determines if the polygons in the range $[poly_first, poly_beyond)$ define a valid y-monotone partition of the polygon represented by the points in the range $[point_first, point_beyond)$. The function returns *true* iff the partition is valid and otherwise returns false.

Precondition: Points in the range $[point_first, point_beyond)$ define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *YMonotonePartitionIsValidTraits_2*.
2. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.
3. *ForwardIterator::value_type* should be *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

 CGAL::is_y_monotone_2 page 749
 CGAL::partition_is_valid_2 page 761
 CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid> page 767

Implementation

This function uses the function *partition_is_valid_2* together with the function object *Is_y_monotone_2* to determine if each polygon is *y*-monotone or not. Thus the time required is $O(n \log n + e \log e)$ where n is the total number of vertices of the partition polygons and e is the total number of edges.

Example

See the example presented with the function *y_monotone_partition_2* for an illustration of the use of this function.

_____ *advanced* _____

YMonotonePartitionIsValidTraits_2

Definition

Requirements of a traits class that is used by *y_monotone_partition_is_valid_2* for testing the validity of a y-monotone partition of a polygon.

Types

All types required by the concept *PartitionIsValidTraits_2* are required except the function object type *Is_valid*. The following type is required instead:

YMonotonePartitionIsValidTraits_2::Is_y_monotone_2

Model of the concept *PolygonIsValid* that tests if a sequence of points is y-monotone or not.

Creation

Only a copy constructor is required.

YMonotonePartitionIsValidTraits_2 traits(& tr);

Operations

The following function that creates an instance of the above predicate object type must exist instead of the function *is_valid_object* required by *PartitionIsValidTraits_2*.

Is_y_monotone_2 traits.is_y_monotone_2_object(t)

Has Models

YMonotonePartitionTraits_2

Definition

Requirements of a traits class to be used with the function `y_monotone_partition_2`.

Generalizes

PartitionTraits_2 page [765](#)

Types

In addition to the types defined for the concept PartitionTraits_2, the following types are also required:

YMonotonePartitionTraits_2:: Line_2

YMonotonePartitionTraits_2:: Compare_x_at_y_2

Predicate object type that provides *CGAL::Comparison_result operator()(Point_2 p, Line_2 h)* to compare the *x* coordinate of *p* and the horizontal projection of *p* on *h*.

YMonotonePartitionTraits_2:: Construct_line_2

Function object type that provides *Line_2 operator()(Point_2 p, Point_2 q)*, which constructs and returns the line defined by the points *p* and *q*.

YMonotonePartitionTraits_2:: Is_horizontal_2

Function object type that provides *bool operator()(Line_2 l)*, which returns *true* iff the line *l* is horizontal.

Creation

A copy constructor and default constructor are required.

YMonotonePartitionTraits_2 traits;

YMonotonePartitionTraits_2 traits(YMonotonePartitionTraits tr);

Operations

In addition to the functions required for the concept PartitionTraits_2, the following functions that create instances of the above function object types must exist.

Construct_line_2 *traits.construct_line_2_object()*

Compare_x_at_y_2 *traits.compare_x_at_y_2_object()*

Is_horizontal_2 *traits.is_horizontal_2_object()*

10.1 Introduction

Polyhedral surfaces in three dimensions are composed of vertices, edges, facets and an incidence relationship on them. The organization beneath is a halfedge data structure, which restricts the class of representable surfaces to orientable 2-manifolds – with and without boundary. If the surface is closed we call it a *polyhedron*, for example, see the above model of a hammerhead:

The polyhedral surface is realized as a container class that manages vertices, halfedges, facets with their incidences, and that maintains the combinatorial integrity of them. It is based on the highly flexible design of the halfedge data structure, see the introduction in Chapter 11 and [Ket99]. However, the polyhedral surface can be used and understood without knowing the underlying design. Some of the examples in this chapter introduce also gradually into first applications of this flexibility.

10.2 Definition

A polyhedral surface $CGAL::Polyhedron_3<PolyhedronTraits_3>$ in three dimensions consists of vertices V , edges E , facets F and an incidence relation on them. Each edge is represented by two halfedges with opposite orientations. The incidences stored with a halfedge are illustrated in the following figure:

Vertices represent points in space. Edges are straight line segments between two endpoints. Facets are planar polygons without holes. Facets are defined by the circular sequence of halfedges along their boundary. The polyhedral surface itself can have holes (with at least two facets surrounding it since a single facet cannot have a hole). The halfedges along the boundary of a hole are called *border halfedges* and have no incident facet. An edge is a *border edge* if one of its halfedges is a border halfedge. A surface is *closed* if it contains no border halfedges. A closed surface is a boundary representation for polyhedra in three dimensions. The convention is that the halfedges are oriented counterclockwise around facets as seen from the outside of the polyhedron. An implication is that the halfedges are oriented clockwise around the vertices. The notion of the solid side of a facet as defined by the halfedge orientation extends to polyhedral surfaces with border edges although they do not define a closed object. If normal vectors are considered for the facets, normals point outwards (following the right-hand rule).

The strict definition can be found in [Ket99]. One implication of this definition is that the polyhedral surface is always an orientable and oriented 2-manifold with border edges, i.e., the neighborhood of each point on the polyhedral surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with boundary can join. Another implication is that the smallest representable surface avoiding self intersections is a triangle (for polyhedral surfaces with border edges) or a tetrahedron (for polyhedra). Boundary representations of orientable 2-manifolds are closed under Euler operations. They are extended with operations that create or close holes in the surface.

Other intersections besides the incidence relation are not allowed. However, this is not automatically verified in the operations, since self intersections are not easy to check efficiently. $CGAL::Polyhedron_3<PolyhedronTraits_3>$ does only maintain the combinatorial integrity of the polyhedral surface (using Euler operations) and does not consider the coordinates of the points or any other geometric information.

$CGAL::Polyhedron_3<PolyhedronTraits_3>$ can represent polyhedral surfaces as well as polyhedra. The interface is designed in such a way that it is easy to ignore border edges and work only with polyhedra.

10.3 Example Programs

The polyhedral surface is based on the highly flexible design of the halfedge data structure. Examples for this flexibility can be found in Section 10.5 and in Section 11.3. This design is not a prerequisite to understand the following examples. See also the Section 10.6 below for some advanced examples.

10.3.1 First Example Using Defaults

The first example instantiates a polyhedron using a kernel as traits class. It creates a tetrahedron and stores the reference to one of its halfedges in a *Halfedge_handle*. Handles, also known as *trivial iterators*, are used to keep references to halfedges, vertices, or facets for future use. There is also a *Halfedge_iterator* type for enumerating halfedges. Such an iterator type can be used wherever a handle is required. Respective *Halfedge_const_handle* and *Halfedge_const_iterator* for a constant polyhedron and similar handles and iterators with *Vertex_* and *Facet_* prefix are provided too.

The example continues with a test if the halfedge actually refers to a tetrahedron. This test checks the connected component referred to by the halfedge *h* and not the polyhedral surface as a whole. This example works only on the combinatorial level of a polyhedral surface. The next example adds the geometry.

```
// file: examples/Polyhedron/polyhedron_prog_simple.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::Halfedge_handle          Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}
```

10.3.2 Example with Geometry in Vertices

We add geometry to our construction of a tetrahedron. Four points are passed as arguments to the construction. This example demonstrates in addition the use of the vertex iterator and the access to the point in the vertices. Note the natural access notation *v->point()*. Similarly, all information stored in a vertex, halfedge, and facet can be accessed with a member function given a handle or iterator. For example, given a halfedge handle *h* we can write *h->next()* to get a halfedge handle to the next halfedge, *h->opposite()* for the opposite halfedge, *h->vertex()* for the incident vertex at the tip of *h*, and so on. The output of the program will be “1 0 0\n0 1 0\n0 0 1\n0 0 0\n”.

```
// file: examples/Polyhedron/polyhedron_prog_tetra.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef Kernel::Point_3                      Point_3;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::Vertex_iterator          Vertex_iterator;
```

```

int main() {
    Point_3 p( 1.0, 0.0, 0.0);
    Point_3 q( 0.0, 1.0, 0.0);
    Point_3 r( 0.0, 0.0, 1.0);
    Point_3 s( 0.0, 0.0, 0.0);

    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    CGAL::set_ascii_mode( std::cout);
    for ( Vertex_iterator v = P.vertices_begin(); v != P.vertices_end(); ++v)
        std::cout << v->point() << std::endl;
    return 0;
}

```

The polyhedron offers a point iterator for convenience. The above for loop simplifies to a single statement by using *std::copy* and the ostream iterator adaptor.

```

std::copy( P.points_begin(), P.points_end(),
           std::ostream_iterator<Point_3>(std::cout, "\n"));

```

10.3.3 Example for Affine Transformation

An affine transformation A can act as a functor transforming points and a point iterator is conveniently defined for polyhedral surfaces. So, assuming we want only the point coordinates of a polyhedron P transformed, *std::transform* does the job in a single line.

```

std::transform( P.points_begin(), P.points_end(), P.points_begin(), A);

```

10.3.4 Example Computing Plane Equations

The polyhedral surface has already provisions to store a plane equation for each facet. However, it does not provide a function to compute plane equations.

This example computes the plane equations of a polyhedral surface. The actual computation is implemented in the `compute_plane_equations` function. Depending on the arithmetic (exact/inexact) and the shape of the facets (convex/non-convex) different methods are useful. We assume here strictly convex facets and exact arithmetic. In our example a homogeneous representation with `int` coordinates is sufficient. The four plane equations of the tetrahedron are the output of the program.

```

// file: examples/Polyhedron/polyhedron_prog_planes.C

#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

struct Plane_equation {
    template <class Facet>

```

```

typename Facet::Plane_3 operator()( Facet& f) {
    typename Facet::Halfedge_handle h = f.halfedge();
    typedef typename Facet::Plane_3 Plane;
    return Plane( h->vertex()->point(),
                 h->next()->vertex()->point(),
                 h->next()->next()->vertex()->point());
}
};

typedef CGAL::Homogeneous<int>      Kernel;
typedef Kernel::Point_3             Point_3;
typedef Kernel::Plane_3             Plane_3;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
                   Plane_equation());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
              std::ostream_iterator<Plane_3>( std::cout, "\n"));
    return 0;
}

```

10.3.5 Example with a Vector Instead of a List Representation

The polyhedron class template has actually four parameters, where three of them have default values. Using the default values explicitly in our examples above for three parameter—ignoring the fourth parameter, which would be a standard allocator for container class— the definition of a polyhedron looks like:

```

typedef CGAL::Polyhedron_3< Traits,
                          CGAL::Polyhedron_items_3,
                          CGAL::HalfedgeDS_default> Polyhedron;

```

The *CGAL::Polyhedron_items_3* class contains the types used for vertices, edges, and facets. The *CGAL::HalfedgeDS_default* class defines the halfedge data structure used, which is a list-based representation in this case. An alternative is a vector-based representation. Using a vector provides random access for the elements in the polyhedral surface and is more space efficient, but elements cannot be deleted arbitrarily. Using a list allows arbitrary deletions, but provides only bidirectional iterators and is less space efficient. The following example creates again a tetrahedron with given points, but in a vector-based representation.

The vector-based representation resizes automatically if the reserved capacity is not sufficient for the new items created. Upon resizing all handles, iterators, and circulators become invalid. Their correct update in the halfedge data structure is costly, thus it is advisable to reserve enough space in advance as indicated with the alternative constructor in the comment.

advanced

Note that the polyhedron and not the underlying halfedge data structure triggers the resize operation, since the resize operation requires some preconditions, such as valid incidences, to be fulfilled that only the polyhedron can guarantee.

advanced

```
// file: examples/Polyhedron/polyhedron_prog_vector.C

#include <CGAL/Cartesian.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Cartesian<double>          Kernel;
typedef Kernel::Point_3                  Point_3;
typedef CGAL::Polyhedron_3< Kernel,
                           CGAL::Polyhedron_items_3,
                           CGAL::HalfedgeDS_vector> Polyhedron;

int main() {
    Point_3 p( 1.0, 0.0, 0.0);
    Point_3 q( 0.0, 1.0, 0.0);
    Point_3 r( 0.0, 0.0, 1.0);
    Point_3 s( 0.0, 0.0, 0.0);

    Polyhedron P;    // alternative constructor: Polyhedron P(4,12,4);
    P.make_tetrahedron( p, q, r, s);
    CGAL::set_ascii_mode( std::cout);
    std::copy( P.points_begin(), P.points_end(),
               std::ostream_iterator<Point_3>( std::cout, "\n"));
    return 0;
}
```

10.3.6 Example with Circulator Writing Object File Format (OFF)

We create a tetrahedron and write it to *std::cout* using the Object File Format (OFF) [Phi96]. This example makes use of STL algorithms (*std::copy*, *std::distance*), STL *std::ostream_iterator*, and CGAL circulators. The polyhedral surface provides convenient circulators for the counterclockwise circular sequence of halfedges around a facet and the clockwise circular sequence of halfedges around a vertex.

However, the computation of the vertex index in the inner loop of the facet output is not advisable with the *std::distance* function, since it takes linear time for non random-access iterators, which leads to quadratic runtime. For better runtime the vertex index needs to be stored separately and computed once before writing the facets. It can be stored, for example, in the vertex itself or in a hash-structure. See also the following Section 10.4 for file I/O.

```
// file: examples/Polyhedron/polyhedron_prog_off.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
```

```

#include <iostream>

typedef CGAL::Simple_cartesian<double>          Kernel;
typedef Kernel::Point_3                         Point_3;
typedef CGAL::Polyhedron_3<Kernel>             Polyhedron;
typedef Polyhedron::Facet_iterator             Facet_iterator;
typedef Polyhedron::Halfedge_around_facet_circulator Halfedge_facet_circulator;

int main() {
    Point_3 p( 0.0, 0.0, 0.0);
    Point_3 q( 1.0, 0.0, 0.0);
    Point_3 r( 0.0, 1.0, 0.0);
    Point_3 s( 0.0, 0.0, 1.0);

    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);

    // Write polyhedron in Object File Format (OFF).
    CGAL::set_ascii_mode( std::cout);
    std::cout << "OFF" << std::endl << P.size_of_vertices() << ' '
               << P.size_of_facets() << " 0" << std::endl;
    std::copy( P.points_begin(), P.points_end(),
               std::ostream_iterator<Point_3>( std::cout, "\n"));
    for ( Facet_iterator i = P.facets_begin(); i != P.facets_end(); ++i) {
        Halfedge_facet_circulator j = i->facet_begin();
        // Facets in polyhedral surfaces are at least triangles.
        CGAL_assertion( CGAL::circulator_size(j) >= 3);
        std::cout << CGAL::circulator_size(j) << ' ';
        do {
            std::cout << ' ' << std::distance(P.vertices_begin(), j->vertex());
        } while ( ++j != i->facet_begin());
        std::cout << std::endl;
    }
    return 0;
}

```

10.3.7 Example Using Euler Operators to Build a Cube

Euler operators are the natural way of modifying polyhedral surfaces. We provide a set of operations for polyhedra: *split_facet()*, *join_facet()*, *split_vertex()*, *join_vertex()*, *split_loop()*, and *join_loop()*. We add further convenient operators, such as *split_edge()*. However, they could be implemented using the six operators above. Furthermore, we provide more operators to work with polyhedral surfaces with border edges, for example, creating and deleting holes. We refer to the references manual for the definition and illustrative figures of the Euler operators.

The following example implements a function that appends a unit cube to a polyhedral surface. To keep track of the different steps during the creation of the cube a sequence of sketches might help with labels for the different handles that occur in the program code. The following Figure shows six selected steps from the creation sequence. These steps are also marked in the program code.

```
// file: examples/Polyhedron/polyhedron_prog_cube.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

template <class Poly>
typename Poly::Halfedge_handle make_cube_3( Poly& P) {
    // appends a cube of size [0,1]^3 to the polyhedron P.
    CGAL_precondition( P.is_valid());
    typedef typename Poly::Point_3      Point;
    typedef typename Poly::Halfedge_handle Halfedge_handle;
    Halfedge_handle h = P.make_tetrahedron( Point( 1, 0, 0),
                                           Point( 0, 0, 1),
                                           Point( 0, 0, 0),
                                           Point( 0, 1, 0));
    Halfedge_handle g = h->next()->opposite()->next();           // Fig. (a)
    P.split_edge( h->next());
    P.split_edge( g->next());
    P.split_edge( g);                                           // Fig. (b)
    h->next()->vertex()->point()      = Point( 1, 0, 1);
    g->next()->vertex()->point()      = Point( 0, 1, 1);
    g->opposite()->vertex()->point() = Point( 1, 1, 0);           // Fig. (c)
    Halfedge_handle f = P.split_facet( g->next(),
                                       g->next()->next()->next()); // Fig. (d)
    Halfedge_handle e = P.split_edge( f);
    e->vertex()->point() = Point( 1, 1, 1);                       // Fig. (e)
    P.split_facet( e, f->next()->next());                         // Fig. (f)
    CGAL_postcondition( P.is_valid());
    return h;
}

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::Halfedge_handle         Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = make_cube_3( P);
    return (P.is_tetrahedron(h) ? 1 : 0);
}
```

10.4 File I/O

Simple file I/O for polyhedral surfaces is already provided in the library. The file I/O considers so far only the topology of the surface and its point coordinates. It ignores a possible plane equation or any user-added attributes, such as color.

The default file format supported in CGAL for output as well as for input is the Object File Format, OFF, with file extension `.off`, which is also understood by GeomView [Phi96]. For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, `set_ascii_mode` and `set_binary_mode` respectively. The modifier `set_pretty_mode` can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments. Both, ASCII and binary format, can be read independent of the stream setting. Since this file format is the default format, `istream` operators are provided for it.

```
#include <CGAL/IO/Polyhedron_istream.h>
```

```
template <class PolyhedronTraits_3>
ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P
```

Additional formats supported for writing are OpenInventor (`.iv`) [Wer94], VRML 1.0 and 2.0 (`.wrl`) [BPP95, VRM96, HW96], and Wavefront Advanced Visualizer object format (`.obj`). Another convenient output function writes a polyhedral surface to a GeomView process spawned from the CGAL program. These output functions are provided as stream operators, now acting on the stream type of the respective format.

```
#include <CGAL/IO/Polyhedron_inventor_ostream.h>
#include <CGAL/IO/Polyhedron_VRML_1_ostream.h>
#include <CGAL/IO/Polyhedron_VRML_2_ostream.h>
#include <CGAL/IO/Polyhedron_geomview_ostream.h>
```

```
template <class PolyhedronTraits_3>
Inventor_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
VRML_1_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
VRML_2_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
Geomview_stream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

All these file formats have in common that they represent a surface as a set of facets. Each facet is a list of indices pointing into a set of vertices. Vertices are represented as coordinate triples. The file I/O for polyhedral surfaces `CGAL::Polyhedron_3` imposes certain restrictions on these formats. They must represent a permissible polyhedral surface, e.g., a 2-manifold and no isolated vertices, see Section 10.1.

Some example programs around the different file formats are provided in the distribution under `examples/Polyhedron_IO/` and `demo/Polyhedron_IO/`. We show an example converting OFF input into VRML 1.0 output.

```
// examples/Polyhedron_IO/polyhedron2vrm1.C
// -----

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/IO/Polyhedron_VRML_1_ostream.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

int main() {
    Polyhedron P;
    std::cin >> P;
    CGAL::VRML_1_ostream out( std::cout);
    out << P;
    return ( std::cin && std::cout) ? 0 : 1;
}
```

10.5 Extending Vertices, Halfedges, and Facets

In Section [10.3.5](#) we have seen how to change the default list representation

```
typedef CGAL::Polyhedron_3< Traits,
                           CGAL::Polyhedron_items_3,
                           CGAL::HalfedgeDS_default> Polyhedron;
```

to a vector based representation of the underlying halfedge data structure. Now we want to look a bit closer at the second template argument, `Polyhedron_items_3`, that specifies what kind of vertex, halfedge, and facet is used. The implementation of `Polyhedron_items_3` looks a bit involved with nested wrapper class templates. But ignoring this technicality, what remains are three local typedefs that define the `Vertex`, the `Halfedge`, and the `Face` for the polyhedral surface. Note that we use here `Face` instead of `facet`. `Face` is the term used for the halfedge data structure. Only the top layer of the polyhedral surface gives alias names renaming `face` to `facet`.

```
class Polyhedron_items_3 {
public:
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base<Refs, CGAL::Tag_true, Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base<Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base<Refs, CGAL::Tag_true, Plane> Face;
    };
};
```

```
};
};
```

If we look up in the reference manual the definitions of the three classes used in the typedefs, we will see the confirmation that the default polyhedron uses all supported incidences, a point in the vertex class, and a plane equation in the face class. Note how the wrapper class provides two template parameters, `Refs`, which we discuss a bit later, and `Traits`, which is the geometric traits class used by the polyhedral surface and which provides us here with the types for the point and the plane equation.

Using this example code we can write our own items class. Instead, we illustrate an easier way if we only want to exchange one class. We use a simpler face without the plane equation but with a color attribute added. To simplify the creation of a vertex, halfedge, or face class, it is always recommended to derive from one of the given base classes. Even if the base class would contain no data it would provide convenient type definitions. So, we derive from the base class, repeat the mandatory constructors if necessary—which is not the case for faces but would be for vertices—and add the color attribute.

```
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};
```

The new items class is derived from the old items class and the wrapper containing the face typedef gets overridden. Note that the name of the wrapper and its template parameters are fixed. They cannot be changed even if, as in this example, a template parameter is not used.

```
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};
```

When we use our new items class with the polyhedral surface, our new face class is used in the halfedge data structure and the color attribute is available in the type `Polyhedron::Facet`. However, `Polyhedron::Facet` is not the same type as our local face typedef for `My_face`, but it is derived therefrom. Thus, everything that we put in the local face type except constructors is then available in the `Polyhedron::Facet` type. For more details, see the Chapter 11 on the halfedge data structure design.

Pulling all pieces together, the full example program illustrates how easy the color attribute can be accessed once it is defined.

```
// file: examples/Polyhedron/polyhedron_prog_color.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
```

```

        CGAL::Color color;
};

// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items> Polyhedron;
typedef Polyhedron::Halfedge_handle         Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}

```

We come back to the first template parameter, *Refs*, of the wrapper classes. This parameter provides us with local types that allow us to make further references between vertices, halfedges, and facets, which have not already been prepared for in the current design. These local types are *Vertex_handle*, *Halfedge_handle*, *Face_handle*, and there respective *..._const_handle*. We add now a new vertex reference to a face class as follows. Encapsulation and access functions could be added for a more thorough design, but we omit that here for the sake of brevity. The integration of the face class with the items class works as illustrated above.

```

template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    typedef typename Refs::Vertex_handle Vertex_handle;
    Vertex_handle vertex_ref;
};

```

More advanced examples can be found in the Section 11.3 illustrating further the design of the halfedge data structure.

10.6 Advanced Example Programs

10.6.1 Example Creating a Subdivision Surface

This program reads a polyhedral surface from the standard input and writes a refined polyhedral surface to the standard output. Input and output are in the Object File Format, OFF, with the common file extension *.off*, which is also understood by GeomView [Phi96].

The refinement is a single step of the $\sqrt{3}$ -scheme for creating a subdivision surface [Kob00]. Each step subdivides a facet into triangles around a new center vertex, smoothes the position of the old vertices, and flips the old edges. The program is organized along this outline. In each of these parts, the program efficiently uses the

knowledge that the newly created vertices, edges, and facets have been added to the end of the sequences. The program needs additional processing memory only for the smoothing step of the old vertices.

The above figure shows three example objects, each subdivided four times. The initial object for the left sequence is the closed surface of three unit cubes glued together to a corner. The example program shown here can handle only closed surfaces, but the extended example `examples/Polyhedron/polyhedron_prog_subdiv_with_boundary.C` handles surfaces with boundary. So, the middle sequence starts with the same surface where one of the facets has been removed. The boundary subdivides to a nice circle. The third sequence creates a sharp edge using a trick in the object presentation. The sharp edge is actually a hole whose vertex coordinates pinch the hole shut to form an edge. The example directory `examples/Polyhedron/` contains the OFF files used here.

```
// file: examples/Polyhedron/polyhedron_prog_subdiv.C

#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <iostream>
#include <algorithm>
#include <vector>
#include <cmath>

typedef CGAL::Cartesian<double>          Kernel;
typedef Kernel::Vector_3                  Vector;
typedef Kernel::Point_3                   Point;
typedef CGAL::Polyhedron_3<Kernel>        Polyhedron;

typedef Polyhedron::Vertex                 Vertex;
typedef Polyhedron::Vertex_iterator        Vertex_iterator;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;
typedef Polyhedron::Edge_iterator          Edge_iterator;
typedef Polyhedron::Facet_iterator         Facet_iterator;
typedef Polyhedron::Halfedge_around_vertex_const_circulator HV_circulator;
```

```

typedef Polyhedron::Halfedge_around_facet_circulator      HF_circulator;

void create_center_vertex( Polyhedron& P, Facet_iterator f) {
    Vector vec( 0.0, 0.0, 0.0);
    std::size_t order = 0;
    HF_circulator h = f->facet_begin();
    do {
        vec = vec + ( h->vertex()->point() - CGAL::ORIGIN);
        ++ order;
    } while ( ++h != f->facet_begin());
    CGAL_assertion( order >= 3); // guaranteed by definition of polyhedron
    Point center = CGAL::ORIGIN + (vec / order);
    Halfedge_handle new_center = P.create_center_vertex( f->halfedge());
    new_center->vertex()->point() = center;
}

struct Smooth_old_vertex {
    Point operator()( const Vertex& v) const {
        CGAL_precondition((CGAL::circulator_size( v.vertex_begin()) & 1) == 0);
        std::size_t degree = CGAL::circulator_size( v.vertex_begin()) / 2;
        double alpha = ( 4.0 - 2.0 * std::cos( 2.0 * CGAL_PI / degree)) / 9.0;
        Vector vec = (v.point() - CGAL::ORIGIN) * ( 1.0 - alpha);
        HV_circulator h = v.vertex_begin();
        do {
            vec = vec + ( h->opposite()->vertex()->point() - CGAL::ORIGIN)
                * alpha / degree;
            ++ h;
            CGAL_assertion( h != v.vertex_begin()); // even degree guaranteed
            ++ h;
        } while ( h != v.vertex_begin());
        return (CGAL::ORIGIN + vec);
    }
};

void flip_edge( Polyhedron& P, Halfedge_handle e) {
    Halfedge_handle h = e->next();
    P.join_facet( e);
    P.split_facet( h, h->next()->next());
}

void subdiv( Polyhedron& P) {
    if ( P.size_of_facets() == 0)
        return;
    // We use that new vertices/halfedges/facets are appended at the end.
    std::size_t nv = P.size_of_vertices();
    Vertex_iterator last_v = P.vertices_end();
    -- last_v; // the last of the old vertices
    Edge_iterator last_e = P.edges_end();
    -- last_e; // the last of the old edges
    Facet_iterator last_f = P.facets_end();
    -- last_f; // the last of the old facets

    Facet_iterator f = P.facets_begin(); // create new center vertices
    do {

```

```

        create_center_vertex( P, f);
    } while ( f++ != last_f);

    std::vector<Point> pts; // smooth the old vertices
    pts.reserve( nv); // get intermediate space for the new points
    ++ last_v; // make it the past-the-end position again
    std::transform( P.vertices_begin(), last_v, std::back_inserter( pts),
        Smooth_old_vertex());
    std::copy( pts.begin(), pts.end(), P.points_begin());

    Edge_iterator e = P.edges_begin(); // flip the old edges
    ++ last_e; // make it the past-the-end position again
    while ( e != last_e) {
        Halfedge_handle h = e;
        ++e; // careful, incr. before flip since flip destroys current edge
        flip_edge( P, h);
    };
    CGAL_postcondition( P.is_valid());
}

int main() {
    Polyhedron P;
    std::cin >> P;
    P.normalize_border();
    if ( P.size_of_border_edges() != 0) {
        std::cerr << "The input object has border edges. Cannot subdivide."
            << std::endl;
        std::exit(1);
    }
    subdiv( P);
    std::cout << P;
    return 0;
}

```

10.6.2 Example Using the Incremental Builder and Modifier Mechanism

A utility class *CGAL::Polyhedron_incremental_builder_3* helps in creating polyhedral surfaces from a list of points followed by a list of facets that are represented as indices into the point list. This is particularly useful for implementing file reader for common file formats. It is used here to create a triangle.

A modifier mechanism allows to access the internal representation of the polyhedral surface, i.e., the halfedge data structure, in a controlled manner. A modifier is basically a callback mechanism using a function object. When called, the function object receives the internal halfedge data structure as a parameter and can modify it. On return, the polyhedron can check the halfedge data structure for validity. Such a modifier object must always return with a halfedge data structure that is a valid polyhedral surface. The validity check is implemented as an expensive postcondition at the end of the *delegate()* member function, i.e., it is not called by default, only when expensive checks are activated.

In this example, *Build_triangle* is such a function object derived from *CGAL::Modifier_base<HalfedgeDS>*. The *delegate()* member function of the polyhedron accepts this function object and calls its *operator()* with a reference to its internally used halfedge data structure. Thus, this member function in *Build_triangle* can create the triangle in the halfedge data structure.

```

// file: examples/Polyhedron/polyhedron_prog_incr_builder.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex    Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>    Kernel;
typedef CGAL::Polyhedron_3<Kernel>        Polyhedron;
typedef Polyhedron::HalfedgeDS            HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}

```

3D Polyhedral Surfaces

Reference Manual

Lutz Kettner

Polyhedral surfaces in three dimensions are composed of vertices, edges, facets and an incidence relationship on them. The organization beneath is a halfedge data structure, which restricts the class of representable surfaces to orientable 2-manifolds – with and without boundary. If the surface is closed we call it a *polyhedron*.

The polyhedral surface is realized as a container class managing vertices, halfedges, facets with their incidences, and maintaining the combinatorial integrity of them. Its local types for the vertices, halfedges and facets are documented separately. A default traits class, a default items class and an incremental builder conclude the references. The polyhedral surface is based on the highly flexible design of the halfedge data structure, see the reference for *HalfedgeDS* in Chapter 11 or [Ket99], but the default instantiation of the polyhedral surface can be used without knowing the halfedge data structure.

CGAL::Polyhedron_3<Traits>

Definition

A polyhedral surface *Polyhedron_3<Traits>* consists of vertices V , edges E , facets F and an incidence relation on them. Each edge is represented by two halfedges with opposite orientations.

Vertices represent points in 3d-space. Edges are straight line segments between two endpoints. Facets are planar polygons without holes defined by the circular sequence of halfedges along their boundary. The polyhedral surface itself can have holes. The halfedges along the boundary of a hole are called *border halfedges* and have no incident facet. An edge is a *border edge* if one of its halfedges is a border halfedge. A surface is *closed* if it contains no border halfedges. A closed surface is a boundary representation for polyhedra in three dimensions. The convention is that the halfedges are oriented counterclockwise around facets as seen from the outside of the polyhedron. An implication is that the halfedges are oriented clockwise around the vertices. The notion of the solid side of a facet as defined by the halfedge orientation extends to polyhedral surfaces with border edges although they do not define a closed object. If normal vectors are considered for the facets, normals point outwards (following the right hand rule).

The strict definition can be found in [Ket99]. One implication of this definition is that the polyhedral surface is always an orientable and oriented 2-manifold with border edges, i.e., the neighborhood of each point on the polyhedral surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with boundary can join. Another implication is that the smallest representable surface is a triangle (for polyhedral surfaces with border edges) or a tetrahedron (for polyhedra). Boundary representations of orientable 2-manifolds are closed under Euler operations. They are extended with operations that create or close holes in the surface.

Other intersections besides the incidence relation are not allowed, although they are not automatically handled, since self intersections are not easy to check efficiently. *Polyhedron_3<Traits>* does only maintain the combinatorial integrity of the polyhedral surface (using Euler operations) and does not consider the coordinates of the points or any geometric information.

The class *Polyhedron_3<Traits>* can represent polyhedral surfaces as well as polyhedra. The interface is designed in such a way that it is easy to ignore border edges and work only with polyhedra.

The sequence of edges can be ordered in the data structure on request such that the sequence starts with the non-border edges and ends with the border edges. Border edges are then itself ordered such that the halfedge which is incident to the facet comes first and the halfedge incident to the hole comes thereafter. This normalization step counts simultaneously the number of border edges. This number is zero if and only if the surface is a closed polyhedron. Note that this class does not maintain this counter nor the halfedge order during further modifications. There is no automatic caching done for auxiliary information.

```
#include <CGAL/Polyhedron_3.h>
```

Parameters

The full template declaration of *Polyhedron_3*<*Traits*> states four template parameters:

```
template < class PolyhedronTraits_3,
           class PolyhedronItems_3 = CGAL::Polyhedron_items_3,
           template < class T, class I> class HalfedgeDS = CGAL::HalfedgeDS_default,
           class Alloc = CGAL_ALLOCATOR(int)>
class Polyhedron_3;
```

The first parameter requires a model of the *PolyhedronTraits_3* concept as argument, for example *CGAL::Polyhedron_traits_3*. The second parameter expects a model of the *PolyhedronItems_3* concept. By default, the class *CGAL::Polyhedron_items_3* is preselected. The third parameter is a class template. A model of the *HalfedgeDS* concept is expected. By default, the class *CGAL::HalfedgeDS_default* is preselected, which is a list based implementation of the halfedge data structure. The fourth parameter *Alloc* requires a standard allocator for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default is provided with the macro *CGAL_ALLOCATOR(int)* from the *<CGAL/memory.h>* header file.

Types

<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Traits</i>	traits class selected for <i>PolyhedronTraits_3</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Items</i>	items class selected for <i>PolyhedronItems_3</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>HalfedgeDS</i>	instantiated halfedge data structure.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>size_type</i>	size type of <i>HalfedgeDS</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>difference_type</i>	difference type of <i>HalfedgeDS</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>iterator_category</i>	iterator category of <i>HalfedgeDS</i> for all iterators.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>circulator_category</i>	circulator category of all circulators; bidirectional category if the <i>Items::Halfedge</i> provides a <i>prev()</i> member function, otherwise forward category.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>allocator_type</i>	allocator type <i>Alloc</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Vertex</i>	vertex type.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Halfedge</i>	halfedge type.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Facet</i>	facet type.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Point_3</i>	point stored in vertices.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Plane_3</i>	plane equation stored in facets (if supported).

The following handles, iterators, and circulators have appropriate non-mutable counterparts, i.e., *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Halfedge_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. For convenience, the *Edge_iterator* enumerates every other halfedge. It is based on the *CGAL::N_step_adaptor* class. For convenience, the *Point_iterator* enumerates all points in the polyhedral surface in the same order as the *Vertex_iterator*, but with the value type *Point*. It is based on the *CGAL::Iterator_project* adaptor. Similarly, a *Plane_iterator* is provided.

<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Vertex_handle</i>	handle to vertex.
--------------------------------------------------------------	-------------------

<i>Polyhedron_3<Traits>:: Halfedge_handle</i>	handle to halfedge.
<i>Polyhedron_3<Traits>:: Facet_handle</i>	handle to facet.
<i>Polyhedron_3<Traits>:: Vertex_iterator</i>	iterator over all vertices.
<i>Polyhedron_3<Traits>:: Halfedge_iterator</i>	iterator over all halfedges.
<i>Polyhedron_3<Traits>:: Facet_iterator</i>	iterator over all facets.
<i>Polyhedron_3<Traits>:: Halfedge_around_vertex_circulator</i>	
	circulator of halfedges around a vertex (cw).
<i>Polyhedron_3<Traits>:: Halfedge_around_facet_circulator</i>	
	circulator of halfedges around a facet (ccw).
<i>Polyhedron_3<Traits>:: Edge_iterator</i>	iterator over all edges (every other halfedge).
<i>Polyhedron_3<Traits>:: Point_iterator</i>	iterator over all points.
<i>Polyhedron_3<Traits>:: Plane_iterator</i>	iterator over all plane equations.

Types for Tagging Optional Features

The following types are equal to either *CGAL::Tag_true* or *CGAL::Tag_false*, depending on whether the named feature is supported or not.

<i>Polyhedron_3<Traits>:: Supports_vertex_halfedge</i>	<i>Vertex::halfedge()</i> .
<i>Polyhedron_3<Traits>:: Supports_vertex_point</i>	<i>Vertex::point()</i> .
<i>Polyhedron_3<Traits>:: Supports_halfedge_prev</i>	<i>Halfedge::prev()</i> .
<i>Polyhedron_3<Traits>:: Supports_halfedge_vertex</i>	<i>Halfedge::vertex()</i> .
<i>Polyhedron_3<Traits>:: Supports_halfedge_facet</i>	<i>Halfedge::facet()</i> .
<i>Polyhedron_3<Traits>:: Supports_facet_halfedge</i>	<i>Facet::halfedge()</i> .
<i>Polyhedron_3<Traits>:: Supports_facet_plane</i>	<i>Facet::plane()</i> .
<i>Polyhedron_3<Traits>:: Supports_removal</i>	supports removal of individual elements.

— advanced —

Creation

Polyhedron_3<Traits> *P*(*Traits traits* = *Traits()*);

Polyhedron_3<Traits> *P*(*size_type v*, *size_type h*, *size_type f*, *Traits traits* = *Traits()*);

a polyhedron *P* with storage reserved for *v* vertices, *h* halfedges, and *f* facets.
The reservation sizes are a hint for optimizing storage allocation.

void *P.reserve*(*size_type v*, *size_type h*, *size_type f*)

reserve storage for *v* vertices, *h* halfedges, and *f* facets. The reservation sizes are a hint for optimizing storage allocation. If the *capacity* is already greater than the requested size nothing happens. If the *capacity* changes all iterators and circulators might invalidate.

<i>Halfedge_handle</i>	<i>P.make_tetrahedron()</i>	a tetrahedron is added to the polyhedral surface. Returns a halfedge of the tetrahedron.
<i>Halfedge_handle</i>	<i>P.make_tetrahedron(Point p1, Point p2, Point p3, Point p4)</i>	a tetrahedron is added to the polyhedral surface with its vertices initialized to p_1, p_2, p_3 , and p_4 . Returns that halfedge of the tetrahedron which incident vertex is initialized to p_1 . The incident vertex of the next halfedge is p_2 , and the vertex thereafter is p_3 . The remaining fourth vertex is initialized to p_4 .
<i>Halfedge_handle</i>	<i>P.make_triangle()</i>	a triangle with border edges is added to the polyhedral surface. Returns a non-border halfedge of the triangle.
<i>Halfedge_handle</i>	<i>P.make_triangle(Point p1, Point p2, Point p3)</i>	a triangle with border edges is added to the polyhedral surface with its vertices initialized to p_1, p_2 , and p_3 . Returns that non-border halfedge of the triangle which incident vertex is initialized to p_1 . The incident vertex of the next halfedge is p_2 , and the vertex thereafter is p_3 .

Access Member Functions

<i>bool</i>	<i>P.empty()</i>	returns true if P is empty.
<i>size_type</i>	<i>P.size_of_vertices()</i>	number of vertices.
<i>size_type</i>	<i>P.size_of_halfedges()</i>	number of halfedges (incl. border halfedges).
<i>size_type</i>	<i>P.size_of_facets()</i>	number of facets.
<i>size_type</i>	<i>P.capacity_of_vertices()</i>	space reserved for vertices.
<i>size_type</i>	<i>P.capacity_of_halfedges()</i>	space reserved for halfedges.
<i>size_type</i>	<i>P.capacity_of_facets()</i>	space reserved for facets.
<i>size_t</i>	<i>P.bytes()</i>	bytes used for the polyhedron.
<i>size_t</i>	<i>P.bytes_reserved()</i>	bytes reserved for the polyhedron.
<i>allocator_type</i>	<i>P.get_allocator()</i>	allocator object.
<i>Vertex_iterator</i>	<i>P.vertices_begin()</i>	iterator over all vertices.

<i>Halfedge_iterator</i>	<i>P.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_iterator</i>	<i>P.halfedges_end()</i>	past-the-end iterator.
<i>Facet_iterator</i>	<i>P.facets_begin()</i>	iterator over all facets (excluding holes).
<i>Facet_iterator</i>	<i>P.facets_end()</i>	past-the-end iterator.
<i>Edge_iterator</i>	<i>P.edges_begin()</i>	iterator over all edges.
<i>Edge_iterator</i>	<i>P.edges_end()</i>	past-the-end iterator.

<i>Point_iterator</i>	<i>P.points_begin()</i>	iterator over all points.
<i>Point_iterator</i>	<i>P.points_end()</i>	past-the-end iterator.
<i>Plane_iterator</i>	<i>P.planes_begin()</i>	iterator over all plane equations.
<i>Plane_iterator</i>	<i>P.planes_end()</i>	past-the-end iterator.
<i>Traits</i>	<i>P.traits()</i>	returns the traits class.

Combinatorial Predicates

<i>bool</i>	<i>P.is_closed()</i>	returns <i>true</i> if there are no border edges.
<i>bool</i>	<i>P.is_pure_bivalent()</i>	returns <i>true</i> if all vertices have exactly two incident edges.
<i>bool</i>	<i>P.is_pure_trivalent()</i>	returns <i>true</i> if all vertices have exactly three incident edges.
<i>bool</i>	<i>P.is_pure_triangle()</i>	returns <i>true</i> if all facets are triangles.
<i>bool</i>	<i>P.is_pure_quad()</i>	returns <i>true</i> if all facets are quadrilaterals.
<i>bool</i>	<i>P.is_triangle(Halfedge_const_handle h)</i>	<i>true</i> iff the connected component denoted by <i>h</i> is a triangle.
<i>bool</i>	<i>P.is_tetrahedron(Halfedge_const_handle h)</i>	<i>true</i> iff the connected component denoted by <i>h</i> is a tetrahedron.

Euler Operators (Combinatorial Modifications)

The following Euler operations modify consistently the combinatorial structure of the polyhedral surface. The geometry remains unchanged.

Halfedge_handle $P.\text{split_facet}(\text{Halfedge_handle } h, \text{Halfedge_handle } g)$

splits the facet incident to h and g into two facets with a new diagonal between the two vertices denoted by h and g respectively. The second (new) facet is a copy of the first facet. Returns $h\text{->next}()$ after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from h to g around the facet.

Precondition: h and g are incident to the same facet. $h \neq g$ (no loops). $h\text{->next}() \neq g$ and $g\text{->next}() \neq h$ (no multi-edges).

Halfedge_handle $P.\text{join_facet}(\text{Halfedge_handle } h)$

joins the two facets incident to h . The facet incident to $h\text{->opposite}()$ gets removed. Both facets might be holes. Returns the predecessor of h around the facet. The invariant $\text{join_facet}(\text{split_facet}(h, g))$ returns h and keeps the polyhedron unchanged. The time is proportional to the size of the facet removed and the time to compute $h\text{->prev}()$.

Precondition: The degree of both vertices incident to h is at least three (no antennas).

Requirement: $\text{Supports_removal} \equiv \text{CGAL::Tag_true}$.

Halfedge_handle $P.\text{split_vertex}(\text{Halfedge_handle } h, \text{Halfedge_handle } g)$

splits the vertex incident to h and g into two vertices, the old vertex remains and a new copy is created, and connects them with a new edge. Let h_{new} be $h\text{->next}()\text{->opposite}()$ after the split, i.e., a halfedge of the new edge. The split regroupes the halfedges around the two vertices. The halfedge sequence $h_{\text{new}}, g\text{->next}()\text{->opposite}(), \dots, h$ remains around the old vertex, while the halfedge sequence $h_{\text{new}}\text{->opposite}(), h\text{->next}()\text{->opposite}()$ (before the split), \dots, g is regrouped around the new vertex. The split returns h_{new} , i.e., the new halfedge incident to the old vertex. The time is proportional to the distance from h to g around the vertex.

Precondition: h and g are incident to the same vertex. $h \neq g$ (antennas are not allowed).

Note: A special application of the split is $\text{split_vertex}(h, h\text{->next}()\text{->opposite}())$ which is equivalent to an edge split of the halfedge $h\text{->next}()$ that creates a new vertex on the halfedge $h\text{->next}()$. See also $\text{split_edge}(h)$ below.

Halfedge_handle *P.join_vertex(Halfedge_handle h)*

joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join_vertex(split_vertex(h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.

Precondition: The size of both facets incident to *h* is at least four (no multi-edges).

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Halfedge_handle *P.split_edge(Halfedge_handle h)*

splits the halfedge *h* into two halfedges inserting a new vertex that is a copy of *h->opposite()->vertex()*. Is equivalent to *split_vertex(h->prev(), h->opposite())*. The call of *prev()* can make this method slower than a direct call of *split_vertex()* if the previous halfedge is already known and computing it would be costly when the halfedge data structure does not support the *prev()* member function. Returns the new halfedge *hnew* pointing to the inserted vertex. The new halfedge is followed by the old halfedge, i.e., *hnew->next() == h*.

Halfedge_handle *P.flip_edge(Halfedge_handle h)*

performs an edge flip. It returns *h* after rotating the edge *h* one vertex in the direction of the face orientation.

Precondition: *h != Halfedge_handle()* and both facets incident to *h* are triangles.

Halfedge_handle *P.create_center_vertex(Halfedge_handle h)*

barycentric triangulation of *h->facet()*. Creates a new vertex, a copy of *h->vertex()*, and connects it to each vertex incident to *h->facet()* splitting *h->facet()* into triangles. *h* remains incident to the original facet, all other triangles are copies of this facet. Returns the halfedge *h->next()* after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the facet.

Precondition: *h* is not a border halfedge.

Halfedge_handle *P.erase_center_vertex(Halfedge_handle g)*

reverses *create_center_vertex*. Erases the vertex pointed to by *g* and all incident halfedges thereby merging all incident facets. Only *g->facet()* remains. The neighborhood of *g->vertex()* may not be triangulated, it can have larger facets. Returns the halfedge *g->prev()*. Thus, the invariant *h == erase_center_vertex(create_center_vertex(h))* holds if *h* is not a border halfedge. The time is proportional to the sum of the size of all incident facets.

Precondition: None of the incident facets of *g->vertex()* is a hole. There are at least two distinct facets incident to the facets that are incident to *g->vertex()*. (This prevents the operation from collapsing a volume into two facets glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Euler Operators Modifying Genus

Halfedge_handle *P.split_loop(Halfedge_handle h, Halfedge_handle i, Halfedge_handle j)*

cuts the polyhedron into two parts along the cycle (h, i, j) (edge j runs on the backside of the three dimensional figure above). Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created. h, i, j will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of $h_opposite()$.

Precondition: h, i, j denote distinct, consecutive vertices of the polyhedron and form a cycle: i.e., $h->vertex() == i->opposite()->vertex(), \dots, j->vertex() == h->opposite()->vertex()$. The six facets incident to h, i, j are all distinct.

Halfedge_handle *P.join_loop(Halfedge_handle h, Halfedge_handle g)*

glues the boundary of the two facets denoted by h and g together and returns h . Both facets and the vertices along the facet denoted by g gets removed. Both facets may be holes. The invariant $join_loop(h, split_loop(h, i, j))$ returns h and keeps the polyhedron unchanged.

Precondition: The facets denoted by h and g are different and have equal degree (i.e., number of edges).

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Modifying Facets and Holes

Halfedge_handle *P.make_hole(Halfedge_handle h)*

removes the incident facet of *h* and changes all halfedges incident to the facet into border edges. Returns *h*. See *erase_facet(h)* for a more generalized variant.

Precondition: None of the incident halfedges of the facet is a border edge.

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Halfedge_handle *P.fill_hole(Halfedge_handle h)*

fills a hole with a newly created facet. Makes all border halfedges of the hole denoted by *h* incident to the new facet. Returns *h*.

Precondition: *h.is_border()*.

Halfedge_handle *P.add_vertex_and_facet_to_border(Halfedge_handle h, Halfedge_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the tip of *g* with the tip of *h* with two new halfedges and a new vertex and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet and the new vertex.

Precondition: *h->is_border()*, *g->is_border()*, *h != g*, and *g* can be reached along the same hole starting with *h*.

Halfedge_handle *P.add_facet_to_border(Halfedge_handle h, Halfedge_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the vertex denoted by *g* with the vertex denoted by *h* with a new halfedge and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet.

Precondition: *h->is_border()*, *g->is_border()*, *h != g*, *h->next() != g*, and *g* can be reached along the same hole starting with *h*.

Erasing

<i>void</i>	<i>P.erase_facet(Halfedge_handle h)</i> removes the incident facet of <i>h</i> and changes all halfedges incident to the facet into border edges or removes them from the polyhedral surface if they were already border edges. If this creates isolated vertices they get removed as well. See <i>make_hole(h)</i> for a more specialized variant. <i>Precondition:</i> <i>h->is_border() == false</i> . <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>P.erase_connected_component(Halfedge_handle h)</i> removes the vertices, halfedges, and facets that belong to the connected component of <i>h</i> . <i>Requirement:</i> <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<i>void</i>	<i>P.clear()</i> removes all vertices, halfedges, and facets.

Operations with Border Halfedges

— *advanced* —

Halfedges incident to a hole are called *border halfedges*. An halfedge is a *border edge* if itself or its opposite halfedge are border halfedges. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is_border()* returning a *bool*. Usually, the halfedge data structure supports facets and a *NULL* facet pointer will indicate a border halfedge, but this is not the only possibility. The *is_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter one of the two halfedges is a border halfedge (the first one is a non-border halfedge in conformance with the polyhedral surface definition). The normalization stores the number of border halfedges and the halfedge iterator the border edges start at within the data structure. Halfedge insertion or removal and changing the border status of a halfedge invalidate these values. They are not automatically updated.

<i>void</i>	<i>P.normalize_border()</i> sorts halfedges such that the non-border edges precede the border edges. For each border edge the halfedge iterator will reference the halfedge incident to the facet right before the halfedge incident to the hole.
<i>size_type</i>	<i>P.size_of_border_halfedges()</i> number of border halfedges. <i>Precondition:</i> last <i>normalize_border()</i> call still valid, see above.
<i>size_type</i>	<i>P.size_of_border_edges()</i> number of border edges. Since each border edge of a polyhedral surface has exactly one border halfedge, this number is equal to <i>size_of_border_halfedges()</i> . <i>Precondition:</i> last <i>normalize_border()</i> call still valid, see above.

Halfedge_iterator *P.border_halfedges_begin()*

halfedge iterator starting with the border edges. The range [*halfedges_begin()*, *border_halfedges_begin()*) denotes all non-border halfedges. The range [*border_halfedges_begin()*, *halfedges_end()*) denotes all border edges.
Precondition: last *normalize_border()* call still valid, see above.

Edge_iterator *P.border_edges_begin()*

edge iterator starting with the border edges. The range [*edges_begin()*, *border_edges_begin()*) denotes all non-border edges. The range [*border_edges_begin()*, *edges_end()*) denotes all border edges.
Precondition: last *normalize_border()* call still valid, see above.

└────────── *advanced* ─────────┘

Miscellaneous

void *P.inside_out()*

reverses facet orientations (incl. plane equations if supported).

bool *P.is_valid(bool verbose = false, int level = 0)*

returns *true* if the polyhedral surface is combinatorially consistent. If *verbose* is *true*, statistics are printed to *cerr*. For *level == 1* the normalization of the border edges is checked too. This method checks in particular level 3 of *CGAL::Halfedge_data_structure_decorator::is_valid* from page 11.4 and that each facet is at least a triangle and that the two incident facets of a non-border edge are distinct.

bool *P.normalized_border_is_valid(bool verbose = false)*

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the iterator: The non-border edges precede the border edges and for border edges, the second halfedge is the border halfedge. The halfedge iterator *border_halfedges_begin()* denotes the first border edge. If *verbose* is *true*, statistics are printed to *cerr*.

advanced

```
void P.delegate( CGAL::Modifier_base<HDS>& m)
```

calls the *operator()* of the modifier *m*. See *CGAL::Modifier_base* in the Support Library Manual for a description of modifier design and its usage.

Precondition: The polyhedral surface must be valid when the modifier returns from execution.

Example

This example program instantiates a polyhedron using the default traits class and creates a tetrahedron.

```
// file: examples/Polyhedron/polyhedron_prog_simple.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::Halfedge_handle          Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}
```

CGAL::Polyhedron_3<Traits>::Facet

Definition

A facet optionally stores a plane equation, and a reference to an incident halfedge that points to the facet. Type tags indicate whether these member functions are supported. Figure 10.1 on page 813 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. The circulator is assignable to the *Halfedge_handle*. The circulator is bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise it is of the forward category.

```
#include <CGAL/Polyhedron_3.h>
```

Types

<i>Facet:: Vertex</i>	type of incident vertices.
<i>Facet:: Halfedge</i>	type of incident halfedges.
<i>Facet:: Plane_3</i>	plane equation type stored in facets.

<i>Facet::Vertex_handle</i>	handle to vertex.
<i>Facet::Halfedge_handle</i>	handle to halfedge.
<i>Facet::Facet_handle</i>	handle to facet.
<i>Facet::Halfedge_around_facet_circulator</i>	circulator of halfedges around a facet.

```
Facet:: Vertex_const_handle
Facet:: Halfedge_const_handle
Facet:: Facet_const_handle
Facet:: Halfedge_around_facet_const_circulator
```

<i>Facet::Supports_facet_halfedge</i>	\equiv <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>Facet::Supports_facet_plane</i>	\equiv <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

Creation

Facet f ; default constructor.

Operations available if *Supports_facet_plane* \equiv *CGAL::Tag_true*

<i>Plane_3</i> &	<i>f.plane()</i>	
<i>const Plane_3</i> &	<i>f.plane() const</i>	plane equation.

Operations available if `Supports_facet_halfedge` \equiv `CGAL::Tag_true`

<i>Halfedge_handle</i>	<i>f.halfedge()</i>	
<i>Halfedge_const_handle</i>	<i>f.halfedge() const</i>	an incident halfedge that points to <i>f</i> .

Halfedge_around_facet_circulator

f.facet_begin()

Halfedge_around_facet_const_circulator

f.facet_begin() const

circulator of halfedges around the facet (counterclockwise).

void

f.set_halfedge(Halfedge_handle h)

sets incident halfedge to *h*.

Precondition: *h* is incident, i.e., *h->facet() == f*.

std::size_t

f.facet_degree() const

the degree of the facet, i.e., number of edges on the boundary of this facet.

bool

f.is_triangle() const

returns *true* if the facet is a triangle.

bool

f.is_quad() const

returns *true* if the facet is a quadrilateral.

CGAL::Polyhedron_3<Traits>::Halfedge

Definition

Figure 10.1 on page 813 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. If a halfedge is incident to a facet the *next()* member function points to the successor halfedge around this facet. For border edges the *next()* member function points to the successor halfedge along the hole. For more than two border edges at a vertex, the next halfedge along a hole is not uniquely defined, but a consistent assignment of the next halfedge will be maintained in the data structure. An invariant is that successive assignments of the form $h = h \rightarrow \text{next}()$ cycle counterclockwise around the facet (or hole) and traverse all halfedges incident to this facet (or hole). A similar invariant is that successive assignments of the form $h = h \rightarrow \text{next}() \rightarrow \text{opposite}()$ cycle clockwise around the vertex and traverse all halfedges incident to this vertex. Two circulators are provided for these circular orders.

Figure 10.1: The three classes *Vertex*, *Halfedge*, and *Facet* of the polyhedral surface. Member functions with shaded background are mandatory. The others are optionally supported.

The incidences encoded in *opposite()* and *next()* are available for each instantiation of polyhedral surfaces. The other incidences are optionally available as indicated with type tags. The *prev()* member function points to the preceding halfedge around the same facet. It is always available, though it might perform a search around the facet using the *next()* member function to find the previous halfedge if the underlying halfedge data structure does not provide an efficient *prev()* member function for halfedges. Handles to the incident vertex and facet are optionally stored.

The circulators are assignable to the *Halfedge_handle*. The circulators are bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise they are of the forward category.

```
#include <CGAL/Polyhedron_3.h>
```

Types

Halfedge::Vertex

Halfedge::Facet

Halfedge:: Supports_halfedge_vertex \equiv *CGAL::Tag_true* or *CGAL::Tag_false*.
Halfedge:: Supports_halfedge_face \equiv *CGAL::Tag_true* or *CGAL::Tag_false*.

Creation

Halfedge h; default constructor.

Operations

Halfedge_handle *h.opposite()*
Halfedge_const_handle *h.opposite() const* the opposite halfedge.

Halfedge_handle *h.next()*
Halfedge_const_handle *h.next() const* the next halfedge around the facet.

Halfedge_handle *h.prev()*
Halfedge_const_handle *h.prev() const* the previous halfedge around the facet.

Halfedge_handle *h.next_on_vertex()*
Halfedge_const_handle *h.next_on_vertex() const* the next halfedge around the vertex (clockwise). Is equal to *h.next()->opposite()*.

Halfedge_handle *h.prev_on_vertex()*
Halfedge_const_handle *h.prev_on_vertex() const* the previous halfedge around the vertex (counterclockwise). Is equal to *h.opposite()->prev()*.

bool *h.is_border() const* is true if *h* is a border halfedge.
bool *h.is_border_edge() const* is true if *h* or *h.opposite()* is a border halfedge.

Halfedge_around_vertex_circulator

h.vertex_begin()

Halfedge_around_vertex_const_circulator

h.vertex_begin() const circulator of halfedges around the vertex (clockwise).

Halfedge_around_facet_circulator

h.facet_begin()

Halfedge_around_facet_const_circulator

	<i>h.facet_begin() const</i>	circulator of halfedges around the facet (counterclockwise).
<i>std::size_t</i>	<i>h.vertex_degree() const</i>	the degree of the incident vertex, i.e., number of edges emanating from this vertex.
<i>bool</i>	<i>h.is_bivalent() const</i>	returns <i>true</i> if the incident vertex has exactly two incident edges.
<i>bool</i>	<i>h.is_trivalent() const</i>	returns <i>true</i> if the incident vertex has exactly three incident edges.
<i>std::size_t</i>	<i>h.facet_degree() const</i>	the degree of the incident facet, i.e., number of edges on the boundary of this facet.
<i>bool</i>	<i>h.is_triangle() const</i>	returns <i>true</i> if the incident facet is a triangle.
<i>bool</i>	<i>h.is_quad() const</i>	returns <i>true</i> if the incident facet is a quadrilateral.

Operations available if *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*

<i>Vertex_handle</i>	<i>h.vertex()</i>	
<i>Vertex_const_handle</i>	<i>h.vertex() const</i>	the incident vertex of <i>h</i> .

Operations available if *Supports_halfedge_facet* \equiv *CGAL::Tag_true*

<i>Facet_handle</i>	<i>h.facet()</i>	
<i>Facet_const_handle</i>	<i>h.facet() const</i>	the incident facet of <i>h</i> . If <i>h</i> is a border halfedge the result is default construction of the handle.

CGAL::Polyhedron_incremental_builder_3<HDS>

Definition

The auxiliary class *Polyhedron_incremental_builder_3<HDS>* supports the incremental construction of polyhedral surfaces, which is for example convenient when constructing polyhedral surfaces from file formats, such as the Object File Format (OFF) [Phi96], OpenInventor [Wer94] or VRML [BPP95, VRM96]. *Polyhedron_incremental_builder_3<HDS>* needs access to the internal halfedge data structure of type *HDS* of the polyhedral surface. It is intended to be used within a modifier, see *CGAL::Modifier_base* in the Support Library Reference Manual.

The incremental builder might be of broader interest for other uses of the halfedge data structures, but it is specifically bound to the definition of polyhedral surfaces given here. During construction all conditions of polyhedral surfaces are checked and in case of violation an error status is set. A diagnostic message will be issued to *cerr* if the *verbose* flag has been set at construction time.

The incremental construction starts with a list of all point coordinates and concludes with a list of all facet polygons. Edges are not explicitly specified. They are derived from the vertex incidence information provided from the facet polygons. The polygons are given as a sequence of vertex indices. The halfedge data structure *HDS* must support vertices (i.e., *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*). Vertices and facets can be added in arbitrary order as long as a call to *add_vertex_to_facet()* refers only to a vertex index that is already known. Some methods return already handles to vertices, facets, and halfedges newly constructed. They can be used to initialize additional fields, however, the incidences in the halfedge-data structure are not stable and are not allowed to be changed.

The incremental builder can work in two modes: *RELATIVE_INDEXING* (the default), in which a polyhedral surface already contained in the halfedge data structure is ignored and all indices are relative to the newly added surface, or *ABSOLUTE_INDEXING*, in which all indices are absolute indices including an already existing polyhedral surface. The former mode allows to create easily independent connected components, while the latter mode allows to continue the construction of an existing surface, the absolute indexing allows to address existing vertices when creating new facets.

```
#include <CGAL/Polyhedron_incremental_builder_3.h>
```

Types

<i>Polyhedron_incremental_builder_3<HDS>::HalfedgeDS</i>	halfedge data structure <i>HDS</i> .
<i>Polyhedron_incremental_builder_3<HDS>::Point_3</i>	point type of the vertex.
<i>Polyhedron_incremental_builder_3<HDS>::size_type</i>	size type.
<i>typedef typename HalfedgeDS::Vertex_handle</i>	<i>Vertex_handle</i> ;
<i>typedef typename HalfedgeDS::Halfedge_handle</i>	<i>Halfedge_handle</i> ;
<i>typedef typename HalfedgeDS::Face_handle</i>	<i>Facet_handle</i> ;

Constants

```
enum { RELATIVE_INDEXING, ABSOLUTE_INDEXING };
```

two different indexing modes.

Creation

Polyhedron_incremental_builder_3<HDS> *B*(*HDS*& *hds*, *bool verbose* = *false*);

stores a reference to the halfedge data structure *hds* of a polyhedral surface in its internal state. An existing polyhedral surface in *hds* remains unchanged. The incremental builder appends the new polyhedral surface. If *verbose* is *true*, diagnostic messages will be printed to *cerr* in case of malformed input data.

Surface Creation

To build a polyhedral surface, the following regular expression gives the correct and allowed order and nesting of method calls from this section:

begin_surface (*add_vertex* | (*begin_facet add_vertex_to_facet* * *end_facet*)) * *end_surface*

void *B.begin_surface*(*size_type v*,
 size_type f,
 size_type h = 0,
 int mode = *RELATIVE_INDEXING*)

starts the construction. *v* is the number of new vertices to expect, *f* the number of new facets, and *h* the number of new halfedges. If *h* is unspecified (*== 0*) it is estimated using Euler's equation (plus 5% for the so far unknown holes and genus of the object). These values are used to reserve space in the halfedge data structure *hds*. If the representation supports insertion these values do not restrict the class of constructible polyhedra. If the representation does not support insertion the object must fit into the reserved sizes. If *mode* is set to *ABSOLUTE_INDEXING* the incremental builder uses absolute indexing and the vertices of the old polyhedral surface can be used in new facets (needs preprocessing time linear in the size of the old surface). Otherwise relative indexing is used starting with new indices for the new construction.

Vertex_handle *B.add_vertex*(*Point_3 p*)

adds a new vertex for *p* and returns its handle.

Facet_handle *B.begin_facet*() starts a new facet and returns its handle.

void *B.add_vertex_to_facet*(*size_type i*)

adds a vertex with index *i* to the current facet. The first point added with *add_vertex()* has the index 0 if *mode* was set to *RELATIVE_INDEXING*, otherwise the first vertex in the referenced *hds* has the index 0.

<i>Halfedge_handle</i>	<i>B.end_facet()</i>	ends a newly constructed facet. Returns the handle to the halfedge incident to the new facet that points to the vertex added first. The halfedge can be safely used to traverse the halfedge cycle around the new facet.
------------------------	----------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>void</i>	<i>B.end_surface()</i>	ends the construction.
-------------	------------------------	------------------------

Additional Operations

template <class InputIterator>

Halfedge_handle B.add_facet(InputIterator first, InputIterator beyond)

is a synonym for *begin_facet()*, a call to *add_facet()* for each value in the range *[first,beyond)*, and a call to *end_facet()*. Returns the return value of *end_facet()*.

Precondition: The value type of *InputIterator* is *std::size_t*. All indices must refer to vertices already added.

template <class InputIterator>

bool B.test_facet(InputIterator first, InputIterator beyond)

returns *true* if a facet described by the vertex indices in the range *[first,beyond)* can be successfully inserted, e.g., with *add_facet(first,beyond)*.

Precondition: The value type of *InputIterator* is *std::size_t*. All indices must refer to vertices already added.

<i>Vertex_handle</i>	<i>B.vertex(std::size_t i)</i>	
----------------------	---------------------------------	--

returns handle for the vertex of index *i*, or *Vertex_handle* if there is no *i*-th vertex.

<i>bool</i>	<i>B.error()</i>	returns error status of the builder.
-------------	------------------	--------------------------------------

<i>void</i>	<i>B.rollback()</i>	undoes all changes made to the halfedge data structure since the last <i>begin_surface()</i> in relative indexing, and deletes the whole surface in absolute indexing. It needs a new call to <i>begin_surface()</i> to start inserting again.
-------------	---------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>bool</i>	<i>B.check_unconnected_vertices()</i>	returns <i>true</i> if unconnected vertices are detected. If <i>verbose</i> was set to <i>true</i> (see the constructor above) debug information about the unconnected vertices is printed.
-------------	---------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>bool</i>	<i>B.remove_unconnected_vertices()</i>	returns <i>true</i> if all unconnected vertices could be removed successfully. This happens either if no unconnected vertices had appeared or if the halfedge data structure supports the removal of individual elements.
-------------	----------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

CGAL::Modifier_base in the Support Library Reference Manual.

Example

A modifier class creates a new triangle in the halfedge data structure using the incremental builder.

```
// file: examples/Polyhedron/polyhedron_prog_incr_builder.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex    Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>    Kernel;
typedef CGAL::Polyhedron_3<Kernel>        Polyhedron;
typedef Polyhedron::HalfedgeDS            HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}
```

PolyhedronItems_3

Definition

The `PolyhedronItems_3` concept extends the `HalfedgeDSItems` concept on page 879. In addition to the requirements stated there, a model for this concept must fulfill the following requirements for the local `PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex` type and `PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face` type in order to support the point for vertices and the optional plane equation for facets. Note that the items class uses face instead of facet. Only the polyhedral surface renames faces to facets.

Refines

`HalfedgeDSItems` page 859

Types in `PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex`

`Vertex::Point` point type stored in vertices. A `HalfedgeDS` has no dimension, so this type is named `Point` and not `Point_3`.

`Vertex::Supports_vertex_point` \equiv `CGAL::Tag_true`. A point is always required.

Operations

<code>Point&</code>	<code>v.point()</code>	
<code>const Point&</code>	<code>v.point() const</code>	point.

Types in `PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face`

Types for (optionally) associated geometry in faces. If it is not supported the respective type has to be defined, although it can be an arbitrary dummy type, such as `void*` or `Tag_false`.

`Face::Plane` plane type stored in faces. A `HalfedgeDS` has no dimension, so this type is named `Plane` and not `Plane_3`.

`Face::Supports_face_plane` either `CGAL::Tag_true` or `CGAL::Tag_false`.

Operations required if `Supports_face_plane \equiv CGAL::Tag_true`

<code>Plane&</code>	<code>f.plane()</code>	
<code>const Plane&</code>	<code>f.plane() const</code>	plane equation.

<i>CGAL::HalfedgeDS_halfedge_base</i> <Refs>	page 877
<i>CGAL::HalfedgeDS_face_base</i> <Refs>	page 874

Example

We define our own items class based on the available *CGAL::HalfedgeDS_face_base* base class for faces. We derive the *Halfedge_wrapper* without further modifications from the *CGAL::HalfedgeDS_items_2*, replace the *Face_wrapper* definition with our new definition, and also replace the *Vertex_wrapper* with a definition that uses *Point_3* instead of *Point_2* as point type. The result is a model for the *PolyhedronItems_3* concept similar to the available *CGAL::Polyhedron_items_3* class. See also there for another illustrative example.

```
#include <CGAL/HalfedgeDS_bases.h>

struct My_items : public CGAL::HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, CGAL::Tag_true, Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base< Refs, CGAL::Tag_true, Plane> Face;
    };
};
```

CGAL::Polyhedron_items_3

Definition

The class *Polyhedron_items_3* is a model of the *PolyhedronItems_3* concept. It provides definitions for vertices with points, halfedges, and faces with plane equations. The polyhedron traits class must provide the respective types for the point and the plane equation. Vertices and facets both contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_items_3.h>
```

Is Model for the Concepts

PolyhedronItems_3 page [822](#)

Types in *Polyhedron_items_3::Vertex_wrapper<Refs,Traits>::Vertex*

```
typedef Traits::Point_3      Point;
typedef CGAL::Tag_true      Supports_vertex_point;
```

Types in *Polyhedron_items_3::Face_wrapper<Refs,Traits>::Face*

```
typedef Traits::Plane_3      Plane;
typedef CGAL::Tag_true      Supports_face_plane;
```

Creation

Polyhedron_items_3 items; default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

See Also

CGAL::Polyhedron_3<Traits> page [799](#)

CGAL::HalfedgeDS_min_items page [885](#)
CGAL::HalfedgeDS_items_2 page [879](#)

Example

The following example program defines a new face class based on the *CGAL::HalfedgeDS_face_base* and adds a new color member variable. The new face class is used to replace the face definition in the *CGAL::Polyhedron_items_3* class. The main function illustrates the access to the new member variable. See also the *PolyhedronItems_3* concept for another illustrative example.

```

// file: examples/Polyhedron/polyhedron_prog_color.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};

// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items>    Polyhedron;
typedef Polyhedron::Halfedge_handle             Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}

```

CGAL::Polyhedron_min_items_3

Definition

The class *Polyhedron_min_items_3* is a minimal model of the *PolyhedronItems_3* concept. It provides definitions for vertices containing points, halfedges, and faces. The polyhedron traits class must provide the respective type for the point. Vertices and facets both do *not* contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_min_items_3.h>
```

Is Model for the Concepts

PolyhedronItems_3 page [822](#)

Types in *Polyhedron_min_items_3::Vertex_wrapper<Refs,Traits>::Vertex*

```
typedef Traits::Point_3      Point;
typedef CGAL::Tag_true      Supports_vertex_point;
```

Types in *Polyhedron_min_items_3::Face_wrapper<Refs,Traits>::Face*

```
typedef CGAL::Tag_false      Supports_face_plane;
```

Creation

Polyhedron_min_items_3 items; default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

PolyhedronTraits_3

Required types and member functions for the PolyhedronTraits_3 concept. This geometric traits concept is used in the polyhedral surface data structure *CGAL::Polyhedron_3<Traits>*. This concept is a subset of the 3d kernel traits and any CGAL kernel model can be used directly as template argument.

Refines

CopyConstructable, *Assignable*.

Types

PolyhedronTraits_3::Point_3 point type.

PolyhedronTraits_3::Plane_3 plane equation. Even if plane equations are not supported with a particular polyhedral surface this type has to be defined (some dummy type).

PolyhedronTraits_3::Construct_opposite_plane_3

is an unary function object that reverses the plane orientation. Must provide *Plane_3 operator()(Plane_3 plane)* that returns the reversed plane. Required only if plane equations are supported and the *inside_out()* method is used to reverse the polyhedral surface orientation.

Creation

PolyhedronTraits_3 traits(traits2); copy constructor.

PolyhedronTraits_3& traits = traits2 assignment.

Operations

Construct_opposite_plane_3 traits.construct_opposite_plane_3_object()

returns an instance of this function object.

Has Models

CGAL::Polyhedron_traits_3<Kernel> page 828

CGAL::Polyhedron_traits_with_normals_3<Kernel> page 830

All models of the *CGAL::Kernel* concept, e.g., *Simple_cartesian<FieldNumberType>*.

CGAL::Polyhedron_traits_3<Kernel>

Definition

The class *Polyhedron_traits_3<Kernel>* is a model of the *PolyhedronTraits_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron_3<PolyhedronTraits_3>* in terms of the CGAL *Kernel*. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

```
#include <CGAL/Polyhedron_traits_3.h>
```

Is Model for the Concepts

PolyhedronTraits_3 page [827](#)

Types

<i>Polyhedron_traits_3<Kernel>::Kernel</i>	the <i>Kernel</i> model.
<i>typedef Kernel::Point_3</i>	<i>Point_3</i> ;
<i>typedef Kernel::Plane_3</i>	<i>Plane_3</i> ;
<i>typedef Kernel::Construct_opposite_plane_3</i>	<i>Construct_opposite_plane_3</i> ;

Creation

<i>Polyhedron_traits_3<Kernel> traits</i> ;	default constructor, uses <i>Kernel()</i> as local reference to the kernel.
---------------------------------------------------	-----------------------------------------------------------------------------

<i>Polyhedron_traits_3<Kernel> traits(Kernel kernel</i>);	stores <i>kernel</i> as local reference.
-------------------------------------------------------------------	------------------------------------------

Operations

<i>Construct_opposite_plane_3 traits.construct_opposite_plane_3_object()</i>	forwarded to <i>kernel</i> .
------------------------------------------------------------------------------	------------------------------

See Also

CGAL::Polyhedron_traits_with_normals_3<Kernel> page [830](#)

Implementation

Since the *PolyhedronTraits_3* concept is a subset of the 3D kernel concept, this class just forwards the relevant types and access member functions from its template argument. However, it is useful for testing sufficiency of requirements.

Example

Instantiation of a polyhedral surface with the Cartesian kernel based on double coordinates.

```

// file: examples/Polyhedron/polyhedron_prog_simple.C

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}

```

CGAL::Polyhedron_traits_with_normals_3<Kernel>

Definition

The class *Polyhedron_traits_with_normals_3<Kernel>* is a model of the *PolyhedronTraits_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron_3<PolyhedronTraits_3>*. *Polyhedron_traits_with_normals_3<Kernel>* uses the normal vector from *Kernel* for the plane equation in facets. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

```
#include <CGAL/Polyhedron_traits_with_normals_3.h>
```

Is Model for the Concepts

PolyhedronTraits_3 page 827

Types

```

Polyhedron_traits_with_normals_3<Kernel>:: Kernel           the Kernel model.
typedef Kernel::Point_3           Point_3;
typedef Kernel::Vector_3         Plane_3;

```

```
typedef Kernel::Construct_opposite_vector_3 Construct_opposite_plane_3;
```

Creation

Polyhedron_traits_with_normals_3<*Kernel*> traits; default constructor, uses *Kernel*() as
local reference to the kernel.

Polyhedron_traits_with_normals_3<Kernel> traits(*Kernel kernel*); stores *kernel* as local reference.

Operations

<i>Construct_opposite_plane_3</i>	<i>traits.construct_opposite_plane_3_object()</i>	
		forwarded to <i>kernel</i> .

See Also

CGAL::Polyhedron_traits_3<Kernel> page 828

Example

We use this traits class to instantiate a polyhedral surface with a normal vector and no plane equation for each facet. We compute the normal vector assuming exact arithmetic (integers in this example) and convex planar facets.

```

// file: examples/Polyhedron/polyhedron_prog_normals.C

#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_traits_with_normals_3.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

struct Normal_vector {
    template <class Facet>
    typename Facet::Plane_3 operator()( Facet& f) {
        typename Facet::Halfedge_handle h = f.halfedge();
        // Facet::Plane_3 is the normal vector type. We assume the
        // CGAL Kernel here and use its global functions.
        return CGAL::cross_product(
            h->next()->vertex()->point() - h->vertex()->point(),
            h->next()->next()->vertex()->point() - h->next()->vertex()->point());
    }
};

typedef CGAL::Homogeneous<int> Kernel;
typedef Kernel::Point_3 Point_3;
typedef Kernel::Vector_3 Vector_3;
typedef CGAL::Polyhedron_traits_with_normals_3<Kernel> Traits;
typedef CGAL::Polyhedron_3<Traits> Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
        Normal_vector());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
        std::ostream_iterator<Vector_3>( std::cout, "\n"));
    return 0;
}

```

CGAL::operator<<

Definition

This operator writes the polyhedral surface P to the output stream out using the Object File Format, OFF, with file extension `.off`, which is also understood by GeomView [\[Phi96\]](#). The output is in ASCII format. From the polyhedral surface, only the point coordinates and facets are written. Neither normal vectors nor color attributes are used.

For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, `set_ascii_mode` and `set_binary_mode` respectively. The modifier `set_pretty_mode` can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

```
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
template <class PolyhedronTraits_3>
ostream& ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

See Also

`CGAL::Polyhedron_3<Traits>` [page 799](#)
`operator>>` [page 833](#)

CGAL::operator>>

Definition

This operator reads a polyhedral surface in Object File Format, OFF, with file extension `.off`, which is also understood by GeomView [[Phi96](#)], from the input stream *in* and appends it to the polyhedral surface *P*. Only the point coordinates and facets from the input stream are used to build the polyhedral surface. Neither normal vectors nor color attributes are evaluated. If the stream *in* does not contain a permissible polyhedral surface the `ios::badbit` of the input stream *in* is set and *P* remains unchanged.

For OFF an ASCII and a binary format exist. The stream detects the format automatically and can read both.

```
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
template <class PolyhedronTraits_3>
istream& istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P
```

See Also

`CGAL::Polyhedron_3<Traits>` [page 799](#)
`CGAL::Polyhedron_incremental_builder_3<HDS>` [page 818](#)
`operator<<` [page 832](#)

Implementation

This operator is implemented using the modifier mechanism for polyhedral surfaces and the `CGAL::Polyhedron_incremental_builder_3` class, which allows the construction in a single, efficient scan pass of the input and handles also all the possible flexibility of the polyhedral surface.

11.1 Introduction

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence informations of vertices, edges and faces, for example for planar maps, polyhedra, or other orientable, two-dimensional surfaces embedded in arbitrary dimension. Each edge is decomposed into two halfedges with opposite orientations. One incident face and one incident vertex are stored in each halfedge. For each face and each vertex, one incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these informations, for example the halfedge pointers in faces or the storage of faces at all.

The halfedge data structure is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron_3* class in Chapter 10.

The data structure provided here is also known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but

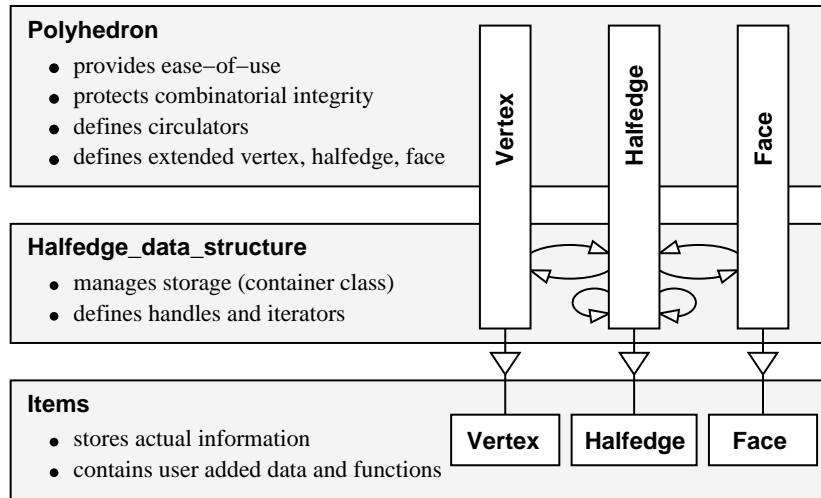

Figure 11.1: Responsibilities of the different layers in the halfedge data-structure design.

the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

The design presented here is a revised and incompatible version of the previous design [Ket98] as used in CGAL R2.2 and earlier releases. Files and identifier names are disjoint with the old design which allows for both versions to co-exists. However, classes using a halfedge data structure can only use one design. For example the polyhedral surface *Polyhedron_3* uses by default the new design. See Chapter 10 for how to still select the old implementation.

11.2 Software Design

Figure 11.1 illustrates the responsibilities of the three layers of the software design, with the *CGAL::Polyhedron_3* as an example for the top layer. The items provide the space for the information that is actually stored, i.e., with member variables and access member functions in *Vertex*, *Halfedge*, and *Face* respectively. Halfedges are required to provide a reference to the next halfedge and to the opposite halfedge. Optionally they may provide a reference to the previous halfedge, to the incident vertex, and to the incident face. Vertices and faces may be empty. Optionally they may provide a reference to the incident halfedge. The options mentioned are supported in the halfedge data structure and the polyhedron, for example, Euler operations update the optional references if they are present. Furthermore, the item classes can be extended with arbitrary attributes and member functions, which will be promoted by inheritance to the actual classes used for the polyhedron.

Vertices, halfedges, and faces are passed as local types of the *Items* class to the halfedge data structure and polyhedron. Implementations for vertices, halfedges and faces are provided that fulfill the mandatory part of the requirements. They can be used as base classes for extensions by the user. Richer implementations are also provided to serve as defaults; for polyhedra they provide all optional incidences, a three-dimensional point in the vertex type and a plane equation in the face type.

The *Halfedge_data_structure*, concept *HalfedgeDS*, is responsible for the storage organization of the items. Currently, implementations using internally a bidirectional list or a vector are provided. The *HalfedgeDS* defines the handles and iterators belonging to the items. These types are promoted to the declaration of the items themselves and are used there to provide the references to the incident items. This promotion of types is done

with a template parameter *Refs* of the item types. The halfedge data structure provides member functions to insert and delete items, to traverse all items, and it gives access to the items.

There are two different models for the *HalfedgeDS* concept available, *HalfedgeDS_list* and *HalfedgeDS_vector*, and more might come. Therefore we have kept their interface small and factored out common functionality into separate helper classes, *HalfedgeDS_decorator*, *HalfedgeDS_const_decorator*, and *HalfedgeDS_items_decorator*, which are not shown in Figure 11.1, but would be placed at the side of the *HalfedgeDS* since they broaden that interface but do not hide it. These helper classes contain operations that are useful to implement the operations in the next layer, for example, the polyhedron. They add, for example, the Euler operations and partial operations from which further Euler operations can be built, such as inserting an edge into the ring of edges at a vertex. Furthermore, the helper classes contain adaptive functionality. For example, if the *prev()* member function is not provided for halfedges, the *find_prev()* member function of a helper class searches in the positive direction along the face for the previous halfedge. But if the *prev()* member function is provided, the *find_prev()* member function simply calls it. This distinction is resolved at compile time with a technique called *compile-time tags*, similar to iterator tags in [SL95].

The *Polyhedron_3* as an example for the third layer adds the geometric interpretation, provides an easy-to-use interface of high-level functions, and unifies the access to the flexibility provided underneath. It renames face to facet, which is more common for three-dimensional surfaces. The interface is designed to protect the integrity of the internal representation, the handles stored in the items can no longer directly be written by the user. The polyhedron adds the convenient and efficient circulators, see the Support Library Manuals, for accessing the circular sequence of edges around a vertex or around a facet. To achieve this, the *Polyhedron_3* derives new vertices, halfedges and facets from those provided in *Items*. These new items are those actually used in the *HalfedgeDS*, which gives us the coherent type structure in this design, especially if compared to our previous design.

11.3 Example Programs

11.3.1 The Default Halfedge Data Structure

The following example program uses the default halfedge data structure and the decorator class. The default halfedge data structure uses a list-based representation. All incidences of the items and a point type for vertices are defined. The trivial traits class provides the type used for the point. The program creates a loop, consisting of two halfedges, one vertex and two faces, and checks its validity.

```
// file: examples/HalfedgeDS/hds_prog_default.C

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL_HALFEDGEDS_DEFAULT<Traits> HDS;
```

```

typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

11.3.2 A Minimal Halfedge Data Structure

The following program defines a minimal halfedge data structure using the minimal items class *CGAL::HalfedgeDS_min_items* and a list-based halfedge data structure. The result is a data structure maintaining only halfedges with next and opposite pointers. No vertices or faces are stored. The data structure represents an *undirected graph*.

```

// file: examples/HalfedgeDS/hds_prog_graph.C

#include <CGAL/HalfedgeDS_min_items.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

// no traits needed, argument can be arbitrary dummy.
typedef CGAL_HALFEDGE_DS_DEFAULT<int, CGAL::HalfedgeDS_min_items> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

11.3.3 The Default with a Vector Instead of a List

The default halfedge data structure uses a list internally and the maximal base classes. We change the list to a vector representation here. Again, a trivial traits class provides the type used for the point. Note that for the vector storage the size of the halfedge data structure should be reserved beforehand, either with the constructor as shown in the example or with the *reserve()* member function. One can later resize the data structure with further calls to the *reserve()* member function, but only if the data structure is in a consistent, i.e., *valid*, state.

Unfortunately this example has also to expose the workaround necessary for compilers that do not support templates as template parameters. The workaround is necessary if the symbolic constant *CGAL_CFG_NO_TMPL_IN_TMPL_PARAM* is set. It uses a member template instead of the class template.

```

// file: examples/HalfedgeDS/hds_prog_vector.C

#include <CGAL/HalfedgeDS_items_2.h>

```

```

#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
typedef CGAL::HalfedgeDS_vector      < Traits, CGAL::HalfedgeDS_items_2> HDS;
#else
typedef CGAL::HalfedgeDS_vector::HDS< Traits, CGAL::HalfedgeDS_items_2> HDS;
#endif
typedef CGAL::HalfedgeDS_decorator<HDS>  Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

11.3.4 Example Adding Color to Faces

This example re-uses the base class available for faces and adds a member variable *color*.

```

// file: examples/HalfedgeDS/hds_prog_color.C

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/IO/Color.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

struct My_traits { // arbitrary point type, not used here.
    typedef int Point_2;
};

typedef CGAL_HALFEDGEDS_DEFAULT <My_traits, My_items> HDS;
typedef HDS::Face Face;
typedef HDS::Face_handle Face_handle;

```

```

int main() {
    HDS hds;
    Face_handle f = hds.faces_push_back( Face( CGAL::RED));
    f->color = CGAL::BLUE;
    CGAL_assertion( f->color == CGAL::BLUE);
    return 0;
}

```

11.3.5 Example Defining a More Compact Halfedge

— *advanced* —

The halfedge data structure as presented here is slightly less space efficient as, for example, the winged-edge data structure [Bau75], the DCEL [MP78] or variants of the quad-edge data structure [GS85]. On the other hand, it does not require any search operations during traversals. A comparison can be found in [Ket99].

The following example trades traversal time for a compact storage representation using traditional C techniques (i.e., type casting and the assumption that pointers, especially those from `malloc` or `new`, point to even addresses). The idea goes as follows: The halfedge data structure allocates halfedges pairwise. Concerning the vector-based data structure this implies that the absolute value of the difference between a halfedge and its opposite halfedge is always one with respect to C pointer arithmetic. We can replace the opposite pointer by a single bit encoding the sign of this difference. We will store this bit as the least significant bit in the next halfedge handle. Furthermore, we do not implement a pointer to the previous halfedge. What remains are three pointers per halfedge.

We use the static member function `halfedge_handle()` to convert from pointers to halfedge handles. The same solution can be applied to the list-based halfedge data structure `CGAL::HalfedgeDS_list`, see `examples/HalfedgeDS/hds_prog_compact2.C`. Here is the example for the vector-based data structure.

```

// file: examples/HalfedgeDS/hds_prog_compact.C

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <cstdint>

// Define a new halfedge class. We assume that the Halfedge_handle can
// be created from a pointer (e.g. the HalfedgeDS is based here on the
// In_place_list or a std::vector with such property) and that halfedges
// are allocated in pairs. We encode the opposite pointer in a single bit,
// which is stored in the lower bit of the next-pointer. We use the
// static member function HDS::halfedge_handle to translate pointer to
// handles.
template <class Refs>
class My_halfedge {
public:
    typedef Refs                                HDS;
    typedef My_halfedge<Refs>                   Base_base;
    typedef My_halfedge<Refs>                   Base;
    typedef My_halfedge<Refs>                   Self;
    typedef CGAL::Tag_false                     Supports_halfedge_prev;

```

```

typedef CGAL::Tag_true Supports_halfedge_vertex;
typedef CGAL::Tag_true Supports_halfedge_face;
typedef typename Refs::Vertex_handle Vertex_handle;
typedef typename Refs::Vertex_const_handle Vertex_const_handle;
typedef typename Refs::Halfedge Halfedge;
typedef typename Refs::Halfedge_handle Halfedge_handle;
typedef typename Refs::Halfedge_const_handle Halfedge_const_handle;
typedef typename Refs::Face_handle Face_handle;
typedef typename Refs::Face_const_handle Face_const_handle;
private:
    std::ptrdiff_t nxt;
public:
    My_halfedge() : nxt(0), f( Face_handle() ) {}

    Halfedge_handle opposite() {
        // Halfedge could be different from My_halfedge (e.g. pointer for
        // linked list). Get proper handle from 'this' pointer first, do
        // pointer arithmetic, then convert pointer back to handle again.
        Halfedge_handle h = HDS::halfedge_handle(this); // proper handle
        if ( nxt & 1)

    }
    void set_next( Halfedge_handle h) {
        CGAL_precondition( ((std::ptrdiff_t)(&*h) & 1) == 0);
        nxt = ((std::ptrdiff_t)(&*h)) | (nxt & 1);
    }
private:    // Support for the Vertex_handle.
    Vertex_handle v;
public:
    // the incident vertex.
    Vertex_handle vertex() { return v; }
    Vertex_const_handle vertex() const { return v; }

```

```

        void                set_vertex( Vertex_handle w) { v = w; }

private:
    Face_handle            f;
public:
    Face_handle            face()                { return f; }
    Face_const_handle      face() const          { return f; }
    void                  set_face( Face_handle g)    { f = g; }
    bool                  is_border() const { return f == Face_handle(); }
};

// Replace halfedge in the default items type.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef My_halfedge<Refs> Halfedge;
    };
};

struct Traits { typedef int Point_2; };
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    typedef CGAL::HalfedgeDS_vector    <Traits, My_items> HDS;
#else
    typedef CGAL::HalfedgeDS_vector::HDS<Traits, My_items> HDS;
#endif
typedef CGAL::HalfedgeDS_decorator<HDS>  Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

└────────── *advanced* ─────────┘

11.3.6 Example Using the Halfedge Iterator

Two edges are created in the default halfedge data structure. The halfedge iterator is used to count the halfedges.

```

// file: examples/HalfedgeDS/hds_prog_halfedge_iterator.C

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL_HALFEDGEDS_DEFAULT<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;
typedef HDS::Halfedge_iterator          Iterator;

int main() {

```

```

HDS hds;
Decorator decorator(hds);
decorator.create_loop();
decorator.create_segment();
CGAL_assertion( decorator.is_valid());
int n = 0;
for ( Iterator i = hds.halfedges_begin(); i != hds.halfedges_end(); ++i )
    ++n;
CGAL_assertion( n == 4); // == 2 edges
return 0;
}

```

11.3.7 Example for an Adapter to Build an Edge Iterator

Three edges are created in the default halfedge data structure. The adapter *N_step_adaptor* is used to declare the edge iterator used in counting the edges.

```

// file: examples/HalfedgeDS/hds_prog_edge_iterator.C

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <CGAL/N_step_adaptor.h>

struct Traits { typedef int Point_2; };
typedef CGAL_HALFEDGEDS_DEFAULT<Traits>          HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>          Decorator;
typedef HDS::Halfedge_iterator                    Halfedge_iterator;
typedef CGAL::N_step_adaptor< Halfedge_iterator, 2> Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
    CGAL_assertion( decorator.is_valid());
    int n = 0;
    for ( Iterator e = hds.halfedges_begin(); e != hds.halfedges_end(); ++e )
        ++n;
    CGAL_assertion( n == 2); // == 2 edges
    return 0;
}

```

Halfedge Data Structure

Reference Manual

Lutz Kettner

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence informations of vertices, edges and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron_3* class in Chapter 10.

The data structure provided here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a related but different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

HalfedgeDS<Traits,Items,Alloc>

Release Note

Beginning with CGAL R2.3, this package has a new design. The old design is still available for backwards compatibility and to support older compiler, such as MSVC++6.0. However its use is deprecated and the manual pages are not converted into this new manual format. Instead, see its old documentation in the manual of deprecated packages. The two designs are not interchangeable.

Definition

The concept of a halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) defines an edge-centered data structure capable of maintaining incidence informations of vertices, edges, and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure.

The data structure defined here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

Each edge is represented by two halfedges with opposite orientations. Each halfedge can store a reference to an incident face and an incident vertex. For each face and each vertex an incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these incidences, for example the reference to halfedges in vertices or the storage of vertices at all. See Figure 11.2 for the incidences, the mandatory and optional member functions possible for vertices, halfedges, and faces.

Figure 11.2: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

A `HalfedgeDS<Traits,Items,Alloc>` organizes the internal storage of its items. Examples are a list-based or a vector-based storage. The `HalfedgeDS<Traits,Items,Alloc>` exhibits most of the characteristics of the container class used internally, for example the iterator category. A vector resizes automatically when a new item exceeds the reserved space. Since resizing is an expensive operation for a `HalfedgeDS<Traits,Items,Alloc>` in general and only possible in a well defined state of the data structure (no dangling handles), it must be called explicitly in advance for a `HalfedgeDS<Traits,Items,Alloc>` before inserting new items beyond the current capacity. Classes built on top of a `HalfedgeDS<Traits,Items,Alloc>` are advised to call the `reserve()` member function before creating new items.

Parameters

A `HalfedgeDS<Traits,Items,Alloc>` is a class template and will be used as argument for other class templates, for example `CGAL::Polyhedron_3`. The template parameters to instantiate the `HalfedgeDS<Traits,Items,Alloc>` will be provided by this other class template. Therefore, the three template parameters and their meaning are mandatory. We distinguish between the template `HalfedgeDS<Traits,Items,Alloc>` and an instantiation of it.

Traits is a traits class that will be passed to the item types in *Items*. It will not be used in `HalfedgeDS<Traits,Items,Alloc>` itself. *Items* is a model of the *HalfedgeDSItems* concept. *Alloc* is a standard allocator that fulfills all requirements of allocators for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default argument is mandatory for *Alloc*, for example, the macro `CGAL_ALLOCATOR(int)` from the `<CGAL/memory.h>` header file can be used as default allocator.

Types

<code>HalfedgeDS<Traits,Items,Alloc>:: Traits</code>	traits class.
<code>HalfedgeDS<Traits,Items,Alloc>:: Items</code>	model of <i>HalfedgeDSItems</i> concept.

<code>HalfedgeDS<Traits,Items,Alloc>:: size_type</code>	size type.
<code>HalfedgeDS<Traits,Items,Alloc>:: difference_type</code>	difference type.
<code>HalfedgeDS<Traits,Items,Alloc>:: iterator_category</code>	iterator category for all iterators.
<code>HalfedgeDS<Traits,Items,Alloc>:: allocator_type</code>	allocator type <i>Alloc</i> .

<code>HalfedgeDS<Traits,Items,Alloc>:: Vertex</code>	model of <i>HalfedgeDSVertex</i> concept.
<code>HalfedgeDS<Traits,Items,Alloc>:: Halfedge</code>	model of <i>HalfedgeDSHalfedge</i> concept.
<code>HalfedgeDS<Traits,Items,Alloc>:: Face</code>	model of <i>HalfedgeDSFace</i> concept.

The following handles and iterators have appropriate non-mutable counterparts, i.e., *const_handle* and *const_iterator*. The mutable types are assignable to their non-mutable counterparts. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. **Note:** The handle types must have a default constructor that creates a unique and always the same handle value. It will be used in analogy to `NULL` for pointers.

<code>HalfedgeDS<Traits,Items,Alloc>:: Vertex_handle</code>	handle to vertex.
<code>HalfedgeDS<Traits,Items,Alloc>:: Halfedge_handle</code>	handle to halfedge.
<code>HalfedgeDS<Traits,Items,Alloc>:: Face_handle</code>	handle to face.

<code>HalfedgeDS<Traits,Items,Alloc>:: Vertex_iterator</code>	iterator over all vertices.
<code>HalfedgeDS<Traits,Items,Alloc>:: Halfedge_iterator</code>	iterator over all halfedges.
<code>HalfedgeDS<Traits,Items,Alloc>:: Face_iterator</code>	iterator over all faces.

Types for Tagging Optional Features

The following types are equal to either `CGAL::Tag_true` or `CGAL::Tag_false`, depending on whether the named feature is supported or not.

<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_vertex_halfedge</i>	<i>Vertex</i> :: <i>halfedge</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_prev</i>	<i>Halfedge</i> :: <i>prev</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_vertex</i>	<i>Halfedge</i> :: <i>vertex</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_face</i>	<i>Halfedge</i> :: <i>face</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_face_halfedge</i>	<i>Face</i> :: <i>halfedge</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_removal</i>	removal of individual elements.

The following dependencies among these options must be regarded:

Vertices are supported \iff *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*.
 Faces are supported \iff *Supports_halfedge_face* \equiv *CGAL::Tag_true*.
Supports_halfedge \equiv *CGAL::Tag_true* \implies *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*.
Supports_vertex_point \equiv *CGAL::Tag_true* \implies *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*.
Supports_face_halfedge \equiv *CGAL::Tag_true* \implies *Supports_halfedge_face* \equiv *CGAL::Tag_true*.

Static Member Functions

When writing an items type, such as a user defined vertex, certain functions need to create a handle but knowing only a pointer, for example, the *this*-pointer. The following static member functions of *HalfedgeDS*<*Traits*,*Items*,*Alloc*> create such a corresponding handle for an item type from a pointer. This conversion encapsulates possible adjustments for hidden data members in the true item type, such as linked-list pointers. Note that the user provides item types with the *Items* template argument, which may differ from the *Vertex*, *Halfedge*, and *Face* types defined in *HalfedgeDS*<*Traits*,*Items*,*Alloc*>. If they differ, they are derived from the user provided item types. We denote the user item types with *Vertex_base*, *Halfedge_base*, and *Face_base* in the following. The fully qualified name for *Vertex_base* would be for example – assuming that the type *Self* refers to the instantiated *HalfedgeDS* –

```
typedef typename Items::template Vertex_wrapper<Self,Traits> Vertex_wrapper;
typedef typename Vertex_wrapper::Vertex Vertex_base;
```

Implementing these functions relies on the fundamental assumption that an iterator (or handle) of the internally used container class can be constructed from a pointer of a contained item only. This is true and controlled by us for *CGAL::In_place_list*. It is true for the *std::vector* of major STL distributions, but not necessarily guaranteed. We might switch to an internal implementation if need arises.

<i>static Vertex_handle</i>	<i>HalfedgeDS</i> :: <i>vertex_handle</i> (<i>Vertex_base</i> * <i>v</i>)
<i>static Vertex_const_handle</i>	<i>HalfedgeDS</i> :: <i>vertex_handle</i> (<i>const Vertex_base</i> * <i>v</i>)
<i>static Halfedge_handle</i>	<i>HalfedgeDS</i> :: <i>halfedge_handle</i> (<i>Halfedge_base</i> * <i>h</i>)
<i>static Halfedge_const_handle</i>	<i>HalfedgeDS</i> :: <i>halfedge_handle</i> (<i>const Halfedge_base</i> * <i>h</i>)
<i>static Face_handle</i>	<i>HalfedgeDS</i> :: <i>face_handle</i> (<i>Face_base</i> * <i>f</i>)
<i>static Face_const_handle</i>	<i>HalfedgeDS</i> :: <i>face_handle</i> (<i>const Face_items</i> * <i>f</i>)

— advanced —

Creation

<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> ;	empty halfedge data structure.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> (<i>size_type</i> <i>v</i> , <i>size_type</i> <i>h</i> , <i>size_type</i> <i>f</i>);	storage reserved for <i>v</i> vertices, <i>h</i> halfedges, and <i>f</i> faces.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> (<i>hds2</i>);	copy constructor. <i>Precondition</i> : <i>hds2</i> contains no dangling handles.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >& <i>hds</i> = <i>hds2</i>	assignment operator. <i>Precondition</i> : <i>hds2</i> contains no dangling handles.
<i>void</i> <i>hds.reserve</i> (<i>size_type</i> <i>v</i> , <i>size_type</i> <i>h</i> , <i>size_type</i> <i>f</i>)	reserves storage for <i>v</i> vertices, <i>h</i> halfedges, and <i>f</i> faces. If all capacities are already greater or equal than the requested sizes nothing happens. Otherwise, <i>hds</i> will be resized and all handles, iterators and circulators invalidate. <i>Precondition</i> : If resizing is necessary <i>hds</i> contains no dangling handles.

Access Member Functions

<i>Size</i>	<i>hds.size_of_vertices</i> ()	number of vertices.
<i>Size</i>	<i>hds.size_of_halfedges</i> ()	number of halfedges.
<i>Size</i>	<i>hds.size_of_faces</i> ()	number of faces.
<i>Size</i>	<i>hds.capacity_of_vertices</i> ()	space reserved for vertices.
<i>Size</i>	<i>hds.capacity_of_halfedges</i> ()	space reserved for halfedges.
<i>Size</i>	<i>hds.capacity_of_faces</i> ()	space reserved for faces.
<i>size_t</i>	<i>hds.bytes</i> ()	bytes used for <i>hds</i> .
<i>size_t</i>	<i>hds.bytes_reserved</i> ()	bytes reserved for <i>hds</i> .
<i>allocator_type</i>	<i>hds.get_allocator</i> ()	allocator object.

The following member functions return the non-mutable iterator if *hds* is declared const.

<i>Vertex_iterator</i>	<i>hds.vertices_begin</i> ()	iterator over all vertices.
<i>Vertex_iterator</i>	<i>hds.vertices_end</i> ()	
<i>Halfedge_iterator</i>	<i>hds.halfedges_begin</i> ()	iterator over all halfedges
<i>Halfedge_iterator</i>	<i>hds.halfedges_end</i> ()	
<i>Face_iterator</i>	<i>hds.faces_begin</i> ()	iterator over all faces.
<i>Face_iterator</i>	<i>hds.faces_end</i> ()	

Insertion

Note that the vertex-related and the face-related member functions may not be provided for a *HalfedgeDS*<*Traits*,*Items*,*Alloc*> that does not support vertices or faces respectively.

Vertex_handle *hds.vertices_push_back(const Vertex& v)*

appends a copy of *v* to *hds*. Returns a handle of the new vertex.

Halfedge_handle *hds.edges_push_back(const Halfedge& h, const Halfedge& g)*

appends a copy of *h* and a copy of *g* to *hds* and makes them opposite to each other. Returns a handle of the copy of *h*.

Halfedge_handle *hds.edges_push_back(const Halfedge& h)*

appends a copy of *h* and a copy of *h*→*opposite()* to *hds* and makes them opposite to each other. Returns a handle of the copy of *h*.
Precondition: h→*opposite()* denotes a halfedge.

Face_handle *hds.faces_push_back(const Face& f)*

appends a copy of *f* to *hds*. Returns a handle of the new face.

Removal

Erasing single elements is optional and indicated with the type tag *Supports_removal*. The *pop_back* and the *clear* member functions are mandatory. If vertices or faces are not supported for a *HalfedgeDS*< Traits, Items, Alloc > the *pop_back* and the *clear* member functions must be provided as null operations.

void *hds.vertices_pop_front()* removes the first vertex if vertices are supported and *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.vertices_pop_back()* removes the last vertex.

void *hds.vertices_erase(Vertex_handle v)* removes the vertex *v* if vertices are supported and *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.vertices_erase(Vertex_handle first, Vertex_handle last)*

removes the range of vertices [*first*, *last*) if vertices are supported and *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.edges_pop_front()* removes the first two halfedges if *Supports_removal* ≡ *CGAL::Tag_true*.

void *hds.edges_pop_back()* removes the last two halfedges.

void *hds.edges_erase(Halfedge_handle h)* removes the pair of halfedges *h* and *h*→*opposite()* if *Supports_removal* ≡ *CGAL::Tag_true*.

<code>void</code>	<code>hds.edges_erase(Halfedge_handle first, Halfedge_handle last)</code>	removes the range of edges $[first, last)$ if <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_pop_front()</code>	removes the first face if faces are supported and <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_pop_back()</code>	removes the last face.
<code>void</code>	<code>hds.faces_erase(Face_handle f)</code>	removes the face <i>f</i> if faces are supported and <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_erase(Face_handle first, Face_handle last)</code>	removes the range of faces $[first, last)$ if faces are supported and <i>Supports_removal</i> \equiv <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.vertices_clear()</code>	removes all vertices.
<code>void</code>	<code>hds.edges_clear()</code>	removes all halfedges.
<code>void</code>	<code>hds.faces_clear()</code>	removes all faces.
<code>void</code>	<code>hds.clear()</code>	removes all elements.

— advanced —

Operations with Border Halfedges

The following notion of *border halfedges* is particular useful where the halfedge data structure is used to model surfaces with boundary, i.e., surfaces with missing faces or open regions. Halfedges incident to an open region are called *border halfedges*. A halfedge is a *border edge* if the halfedge itself or its opposite halfedge is a border halfedge. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is_border()* returning a *bool*. Usually, the halfedge data structure supports faces and the value of the default constructor of the face handle will indicate a border halfedge, but this may not be the only possibility. The *is_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter of the two halfedges is a border halfedge (the first one might be a border halfedge too). The normalization stores the number of border halfedges, as well as the halfedge iterator where the border edges start at, within the halfedge data structure. These values will be invalid after further halfedge insertions or removals and changes in the border status of a halfedge. There is no automatic update required.

<code>void</code>	<code>hds.normalize_border()</code>	sorts halfedges such that the non-border edges precede the border edges. For each border edge that is incident to a face, the halfedge iterator will reference the halfedge incident to the face right before the halfedge incident to the open region.
-------------------	-------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Size *hds.size_of_border_halfedges() const*

number of border halfedges. An edge with no incident face counts as two border halfedges.

Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Size *hds.size_of_border_edges() const*

number of border edges. If *size_of_border_edges()* is equal to *size_of_border_halfedges()* all border edges are incident to a face on one side and to an open region on the other side.

Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Halfedge_iterator *hds.border_halfedges_begin()*

halfedge iterator starting with the border edges. The range [*halfedges_begin()*, *border_halfedges_begin()*) denotes all non-border edges. The range [*border_halfedges_begin()*, *halfedges_end()*) denotes all border edges.

Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Implementation

Classes parameterized with a halfedge data structure, such as *CGAL::Polyhedron_3*, need to declare a class template as one of its template parameters for the *HalfedgeDS<Traits,Items,Alloc>*. For compilers not supporting this (i.e. the flag *CGAL_CFG_NO_TMPL_IN_TMPL_PARAM* is set), the following workaround is required,

which defines a `HalfedgeDS<Traits,Items,Alloc>` as a normal class that contains a member class template named *HDS*, which is the actual halfedge data structure as defined here. The following program fragment illustrates this workaround:

```
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    template <class Traits, class Items, class Alloc>
    class HalfedgeDS {
    public:
        typedef HalfedgeDS<Traits,Items,Alloc> Self;
        HalfedgeDS_vector(); // constructors
#else
    struct HalfedgeDS {
        template <class Traits, class Items, class Alloc>
        class HDS {
        public:
            typedef HDS<Traits,Items,Alloc> Self;
            HDS(); // constructors
#endif
        // ... further member functions. Self denotes the HalfedgeDS.
    };
#endif
#ifdef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    };
#endif
```

HalfedgeDSFace

Definition

The concept `HalfedgeDSFace` defines the requirements for the local *Face* type in the *HalfedgeDS* concept. It is also required in the *Face_wrapper*<*Refs*,*Traits*> member class template of an items class, see the *HalfedgeDSItems* concept.

A face optionally stores a reference to an incident halfedge that points to the face. A type tag indicates whether the related member functions are supported. Figure 11.3 on page 857 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. (The protection can be bypassed by the user, but not by accident.)

Types

<i>HalfedgeDSFace::HalfedgeDS</i>	instantiated <i>HalfedgeDS</i> (\equiv <i>Refs</i>).
<i>HalfedgeDSFace::Base</i>	base class that allows modifications.
<i>HalfedgeDSFace::Vertex</i>	model of <i>HalfedgeDSVertex</i> .
<i>HalfedgeDSFace::Halfedge</i>	model of <i>HalfedgeDSHalfedge</i> .
<i>HalfedgeDSFace::Vertex_handle</i>	handle to vertex.
<i>HalfedgeDSFace::Halfedge_handle</i>	handle to halfedge.
<i>HalfedgeDSFace::Face_handle</i>	handle to face.
<i>HalfedgeDSFace::Vertex_const_handle</i>	
<i>HalfedgeDSFace::Halfedge_const_handle</i>	
<i>HalfedgeDSFace::Face_const_handle</i>	
<i>HalfedgeDSFace::Supports_face_halfedge</i>	<i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

Creation

<i>HalfedgeDSFace f</i> ;	default constructor.
---------------------------	----------------------

Operations available if *Supports_face_halfedge* \equiv *CGAL::Tag_true*

<i>Halfedge_handle</i>	<i>f.halfedge()</i>	
<i>Halfedge_const_handle</i>	<i>f.halfedge() const</i>	incident halfedge that points to <i>f</i> .
<i>void</i>	<i>f.set_halfedge(Halfedge_handle h)</i>	sets incident halfedge to <i>h</i> .

HalfedgeDSHalfedge

Definition

The concept `HalfedgeDSHalfedge` defines the requirements for the local *Halfedge* type in the *HalfedgeDS* concept. It is also required in the *Halfedge_wrapper*<*Refs*,*Traits*> member class template of an items class, see the *HalfedgeDSItems* concept.

A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. The *next()* member function points to the successor halfedge along the face – or if the halfedge is a border halfedge – along the open region. A halfedge optionally stores a reference to the previous halfedge along the face, a reference to an incident vertex, and a reference to an incident face. Type tags indicate whether the related member functions are supported. Figure 11.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

Figure 11.3: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

For the protection of the integrity of the data structure classes such as `CGAL::Polyhedron_3` are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. Even more protection is provided for the *set_opposite()* member function. The base class *Base_base* provides access to it. (The protection could be bypassed also by an user, but not by accident.)

Types

<code>HalfedgeDSHalfedge:: HalfedgeDS</code>	instantiated <i>HalfedgeDS</i> (\equiv <i>Refs</i>).
<code>HalfedgeDSHalfedge:: Base</code>	base class that allows modifications.
<code>HalfedgeDSHalfedge:: Base_base</code>	base class to access <i>set_opposite()</i> .
<code>HalfedgeDSHalfedge:: Vertex</code>	model of <i>HalfedgeDSVertex</i> .
<code>HalfedgeDSHalfedge:: Face</code>	model of <i>HalfedgeDSFace</i> .
<code>HalfedgeDSHalfedge:: Vertex_handle</code>	handle to vertex.
<code>HalfedgeDSHalfedge:: Halfedge_handle</code>	handle to halfedge.
<code>HalfedgeDSHalfedge:: Face_handle</code>	handle to face.
<code>HalfedgeDSHalfedge:: Vertex_const_handle</code>	
<code>HalfedgeDSHalfedge:: Halfedge_const_handle</code>	
<code>HalfedgeDSHalfedge:: Face_const_handle</code>	
<code>HalfedgeDSHalfedge:: Supports_halfedge_prev</code>	<code>CGAL::Tag_true</code> or <code>CGAL::Tag_false</code> .

<i>HalfedgeDSHalfedge:: Supports_halfedge_vertex</i>	~
<i>HalfedgeDSHalfedge:: Supports_halfedge_face</i>	~

Creation

<i>HalfedgeDSHalfedge h;</i>	default constructor.
------------------------------	----------------------

Operations

<i>Halfedge_handle</i>	<i>h.opposite()</i>	
<i>Halfedge_const_handle</i>	<i>h.opposite() const</i>	the opposite halfedge.
<i>void</i>	<i>h.set_opposite(Halfedge_handle h)</i>	sets opposite halfedge to <i>h</i> .
<i>Halfedge_handle</i>	<i>h.next()</i>	
<i>Halfedge_const_handle</i>	<i>h.next() const</i>	the next halfedge around the face.
<i>void</i>	<i>h.set_next(Halfedge_handle h)</i>	sets next halfedge to <i>h</i> .
<i>bool</i>	<i>h.is_border() const</i>	is true if <i>h</i> is a border halfedge.

Operations available if *Supports_halfedge_prev* \equiv *CGAL::Tag_true*

<i>Halfedge_handle</i>	<i>h.prev()</i>	
<i>Halfedge_const_handle</i>	<i>h.prev() const</i>	the previous halfedge around the face.
<i>void</i>	<i>h.set_prev(Halfedge_handle h)</i>	sets prev halfedge to <i>h</i> .

Operations available if *Supports_halfedge_vertex* \equiv *CGAL::Tag_true*

<i>Vertex_handle</i>	<i>h.vertex()</i>	
<i>Vertex_const_handle</i>	<i>h.vertex() const</i>	the incident vertex of <i>h</i> .
<i>void</i>	<i>h.set_vertex(Vertex_handle v)</i>	sets incident vertex to <i>v</i> .

Operations available if *Supports_halfedge_face* \equiv *CGAL::Tag_true*

<i>Face_handle</i>	<i>h.face()</i>	
<i>Face_const_handle</i>	<i>h.face() const</i>	the incident face of <i>h</i> . If <i>h</i> is a border halfedge the result is default construction of the handle.
<i>void</i>	<i>h.set_face(Face_handle f)</i>	sets incident face to <i>f</i> .

HalfedgeDSItems

Definition

The concept `HalfedgeDSItems` wraps the three item types – vertex, halfedge, and face – for a halfedge data structure. A `HalfedgeDSItems` contains three member class templates named `Vertex_wrapper`, `Halfedge_wrapper`, and `Face_wrapper`, each with two template parameters, `Refs` and `Traits`. `Refs` requires an instantiated halfedge data structure `HalfedgeDS` as argument, `Traits` is a geometric traits class supplied by the class that uses the halfedge data structure as internal representation. `Traits` is not used by the halfedge data structure itself. These three member class templates provide a local type named `Vertex`, `Halfedge`, and `Face` respectively. The requirements on these types are described on page 861, page 857, and page 855 respectively.

Types

<code>HalfedgeDSItems::Vertex_wrapper<Refs,Traits>::Vertex</code>	model of <code>HalfedgeDSVertex</code> .
<code>HalfedgeDSItems::Halfedge_wrapper<Refs,Traits>::Halfedge</code>	model of <code>HalfedgeDSHalfedge</code> .
<code>HalfedgeDSItems::Face_wrapper<Refs,Traits>::Face</code>	model of <code>HalfedgeDSFace</code> .

Has Models

Example

The following example shows the canonical implementation of the `CGAL::HalfedgeDS_min_items` class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>    Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
```

```

        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>      Face;
    };
};

```

See page [879](#) for an example implementation of the *CGAL::HalfedgeDS_items_2* class.

CGAL::HalfedgeDS_const_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_const_decorator.h>
```

Inherits From

CGAL::HalfedgeDS_items_decorator<HDS> page 881

Creation

```
HalfedgeDS_const_decorator<HDS> D( const HDS& hds);
```

keeps internally a const reference to *hds*.

Validness Checks

A halfedge data structure has no definition of validness of its own, but a useful set of tests is defined with the following levels:

Level 0 The number of halfedges is even. All pointers except the vertex pointer and the face pointer for border halfedges are unequal to their respective default construction value. For all halfedges *h*: The opposite halfedge is different from *h* and the opposite of the opposite is equal to *h*. The next of the previous halfedge is equal to *h*. For all vertices *v*: the incident vertex of the incident halfedge of *v* is equal to *v*. The halfedges around *v* starting with the incident halfedge of *v* form a cycle. For all faces *f*: the incident face of the incident halfedge of *f* is equal to *f*. The halfedges around *f* starting with the incident halfedge of *f* form a cycle. Redundancies among internal variables are tested, e.g., that iterators enumerate as many items as the related size value indicates.

Level 1 All tests of level 0. For all halfedges *h*: The incident vertex of *h* exists and is equal to the incident vertex of the opposite of the next halfedge. The incident face (or hole) of *h* is equal to the incident face (or hole) of the next halfedge.

Level 2 All tests of level 1. The sum of all halfedges that can be reached through the vertices must be equal to the number of all halfedges, i.e., all halfedges incident to a vertex must form a single cycle.

Level 3 All tests of level 2. The sum of all halfedges that can be reached through the faces must be equal to the number of all halfedges, i.e., all halfedges surrounding a face must form a single cycle (no holes in faces).

Level 4 All tests of level 3 and *normalized_border_is_valid*.

bool

D.is_valid(bool verbose = false, int level = 0)

returns *true* if the halfedge data structure *hds* is valid with respect to the *level* value as defined above. If *verbose* is *true*, statistics are written to *cerr*.

bool

D.normalized_border_is_valid(bool verbose = false)

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the halfedge iterator the following holds: The non-border edges precede the border edges. For border edges, the second halfedge is a border halfedge. (The first halfedge may or may not be a border halfedge.) The halfedge iterator *border_halfedges_begin()* denotes the first border edge. If *verbose* is *true*, statistics are written to *cerr*.

CGAL::HalfedgeDS_decorator<HDS> [page 865](#)

Example

The following program fragment illustrates the implementation of a *is_valid()* member function for a simplified polyhedron class. We assume here that the level three check is the appropriate default for polyhedral surfaces.

```
namespace CGAL {
    template <class Traits>
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        bool is_valid( bool verb = false, int level = 0) const {
            Verbose_ostream verr(verb);
            verr << "begin Polyhedron::is_valid( verb=true, level = " << level
                << "):" << std::endl;
            HalfedgeDS_const_decorator<HDS> decorator(hds);
            bool valid = decorator.is_valid( verb, level + 3);
            // further checks ...
        }
    };
}
```

CGAL::HalfedgeDS_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_decorator.h>
```

Inherits From

CGAL::HalfedgeDS_items_decorator<HDS> page 881

Creation

HalfedgeDS_decorator<HDS> *D*(*HDS& hds*); keeps internally a reference to *hds*.

Creation of New Items

Vertex_handle *D.vertices_push_back*(*Vertex v*) appends a copy of *v* to *hds* if vertices are supported. Returns a handle of the new vertex, or *Vertex_handle()* otherwise.

Face_handle *D.faces_push_back*(*Face f*) appends a copy of *f* to *hds* if faces are supported. Returns a handle of the new face, or *Face_handle()* otherwise.

Creation of New Composed Items

Halfedge_handle *D.create_loop*() returns handle of a halfedge from a newly created loop in *hds* consisting of a single closed edge, one vertex and two faces (if supported respectively).

Halfedge_handle *D.create_segment*() returns a halfedge from a newly created segment in *hds* consisting of a single open edge, two vertices and one face (if supported respectively).

Removal of Elements

The following member functions do *not* update affected incidence relations except if mentioned otherwise.

- void D.vertices_pop_front()* removes the first vertex if vertices are supported.
Requirement: Supports_removal \equiv CGAL::Tag_true.
- void D.vertices_pop_back()* removes the last vertex if vertices are supported.
- void D.vertices_erase(Vertex_handle v)* removes the vertex *v* if vertices are supported.
Requirement: Supports_removal \equiv CGAL::Tag_true.
- void D.vertices_erase(Vertex_handle first, Vertex_handle last)*
removes the range $[first, last)$ if vertices are supported.
Requirement: Supports_removal \equiv CGAL::Tag_true.
- void D.faces_pop_front()* removes the first face if faces are supported.
Requirement: Supports_removal \equiv CGAL::Tag_true.
- void D.faces_pop_back()* removes the last face if faces are supported.
- void D.faces_erase(Face_handle f)* removes the face *f* if faces are supported.
Requirement: Supports_removal \equiv CGAL::Tag_true.
- void D.faces_erase(Face_handle first, Face_handle last)*
removes the range $[first, last)$ if faces are supported.
Requirement: Supports_removal \equiv CGAL::Tag_true.
- void D.erase_face(Halfedge_handle h)* removes the face incident to *h* from *hds* and changes all halfedges incident to the face into border edges or removes them from the halfedge data structure if they were already border edges. If this creates isolated vertices they get removed as well. See *make_hole(h)* for a more specialized variant.
Precondition: h->is_border() == false.
Requirement: If faces are supported, Supports_removal \equiv CGAL::Tag_true.
- void D.erase_connected_component(Halfedge_handle h)*
removes the vertices, halfedges, and faces that belong to the connected component of *h*.
Precondition: For all halfedges g in the connected component g.next() != Halfedge_handle().
Requirement: Supports_removal \equiv CGAL::Tag_true.

Modifying Functions (For Border Halfedges)

- Halfedge_handle D.make_hole(Halfedge_handle h)*
removes the face incident to *h* from *hds* and creates a hole.
Precondition: h != Halfedge_handle() and !(h->is_border()).
Requirement: If faces are supported, Supports_removal \equiv CGAL::Tag_true.

Halfedge_handle *D.fill_hole(Halfedge_handle h)*

fills the hole incident to *h* with a new face from *hds*. Returns *h*.
Precondition: *h* \neq *Halfedge_handle()* and *h->is_border()*.

Halfedge_handle *D.fill_hole(Halfedge_handle h, Face f)*

fills the hole incident to *h* with a copy of face *f*. Returns *h*.
Precondition: *h* \neq *Halfedge_handle()* and *h->is_border()*.

Halfedge_handle *D.add_face_to_border(Halfedge_handle h, Halfedge_handle g)*

extends the surface with a new face from *hds* into the hole incident to *h* and *g*. It creates a new edge connecting the vertex denoted by *g* with the vertex denoted by *h* and fills this separated part of the hole with a new face, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.
Precondition: *h* \neq *Halfedge_handle()*, *g* \neq *Halfedge_handle()*, *h->is_border()*, *g->is_border()* and *g* can be reached along the hole starting with *h*.

Halfedge_handle *D.add_face_to_border(Halfedge_handle h, Halfedge_handle g, Face f)*

extends the surface with a copy of face *f* into the hole incident to *h* and *g*. It creates a new edge connecting the tip of *g* with the tip of *h* and fills this separated part of the hole with a copy of face *f*, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.
Precondition: *h* \neq *Halfedge_handle()*, *g* \neq *Halfedge_handle()*, *h->is_border()*, *g->is_border()* and *g* can be reached along the hole starting with *h*.

Modifying Functions (Euler Operators)

The following Euler operations modify consistently the combinatorial structure of the halfedge data structure. The geometry remains unchanged. Note that well known graph operations are also captured with these Euler operators, for example an edge contraction is equal to a *join_vertex()* operation, or an edge removal to *join_face()*.

Given a halfedge data structure *hds* and a halfedge handle *h* four special applications of the Euler operators are worth mentioning: *split_vertex(h,h)* results in an antenna emanating from the tip of *h*; *split_vertex(h,h->next()->opposite())* results in an edge split of the halfedge *h->next* with a new vertex in-between; *split_face(h,h)* results in a loop directly following *h*; and *split_face(h,h->next())* results in a bridge parallel to the halfedge *h->next* with a new face in-between.

Halfedge_handle *D.split_face(Halfedge_handle h, Halfedge_handle g)*

splits the face incident to *h* and *g* into two faces with a new diagonal between the two vertices denoted by *h* and *g* respectively. The second (new) face obtained from *hds* is a copy of the first face. Returns *h->next()* after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from *h* to *g* around the face.

Halfedge_handle *D.join_face(Halfedge_handle h)*

joins the two faces incident to *h*. The face incident to *h->opposite()* gets removed from *hds*. Both faces might be holes. Returns the predecessor of *h* around the face. The invariant *join_face(split_face(h, g))* returns *h* and keeps the data structure unchanged. The time is proportional to the size of the face removed and the time to compute *h->prev()*.

Requirement: Supports_removal \equiv *CGAL::Tag_true*.

Halfedge_handle *D.split_vertex(Halfedge_handle h, Halfedge_handle g)*

splits the vertex incident to *h* and *g* into two vertices and connects them with a new edge. The second (new) vertex obtained from *hds* is a copy of the first vertex. Returns *h->next()->opposite()* after the operation, i.e., the new edge in the orientation towards the new vertex. The time is proportional to the distance from *h* to *g* around the vertex.

Halfedge_handle *D.join_vertex(Halfedge_handle h)*

joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed by *hds*. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join_vertex(split_vertex(h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.

Requirement: Supports_removal \equiv *CGAL::Tag_true*.

Halfedge_handle *D.create_center_vertex(Halfedge_handle h)*

barycentric triangulation of $h \rightarrow \text{face}()$. Creates a new vertex, a copy of $h \rightarrow \text{vertex}()$, and connects it to each vertex incident to $h \rightarrow \text{face}()$ splitting $h \rightarrow \text{face}()$ into triangles. h remains incident to the original face, all other triangles are copies of this face. Returns the halfedge $h \rightarrow \text{next}()$ after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the face.

Precondition: h is not a border halfedge.

Halfedge_handle *D.erase_center_vertex(Halfedge_handle g)*

reverses *create_center_vertex*. Erases the vertex pointed to by g and all incident halfedges thereby merging all incident faces. Only $g \rightarrow \text{face}()$ remains. The neighborhood of $g \rightarrow \text{vertex}()$ may not be triangulated, it can have larger faces. Returns the halfedge $g \rightarrow \text{prev}()$. Thus, the invariant $h == \text{erase_center_vertex}(\text{create_center_vertex}(h))$ holds if h is not a border halfedge. The time is proportional to the sum of the size of all incident faces.

Precondition: None of the incident faces of $g \rightarrow \text{vertex}()$ is a hole. There are at least two distinct faces incident to the faces that are incident to $g \rightarrow \text{vertex}()$. (This prevents the operation from collapsing a volume into two faces glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Halfedge_handle *D.split_loop(Halfedge_handle h, Halfedge_handle i, Halfedge_handle j)*

cuts the halfedge data structure into two parts along the cycle (h, i, j) . Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created. h, i, j will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of h -*opposite()*.

Precondition: h, i, j denote distinct, consecutive vertices of the halfedge data structure and form a cycle: i.e., $h \rightarrow \text{vertex}() == i \rightarrow \text{opposite}() \rightarrow \text{vertex}(), \dots, j \rightarrow \text{vertex}() == h \rightarrow \text{opposite}() \rightarrow \text{vertex}()$.

Halfedge_handle *D.join_loop(Halfedge_handle h, Halfedge_handle g)*

glues the boundary of the two faces denoted by h and g together and returns h . Both faces and the vertices along the face denoted by g gets removed. Both faces may be holes. The invariant $\text{join_loop}(h, \text{split_loop}(h, i, j))$ returns h and keeps the data structure unchanged.

Precondition: The faces denoted by h and g are different and have equal degree (i.e., number of edges).

Requirement: *Supports_removal* \equiv *CGAL::Tag_true*.

Validness Checks

These operations are the same as for *CGAL::HalfedgeDS_const_decorator<HDS>*. See their documentation on page 863.

bool *D.is_valid(bool verbose = false, int level = 0)*

bool *D.normalized_border_is_valid(bool verbose = false)*

Miscellaneous

void *D.inside_out()* reverses face orientations.
Precondition: *is_valid()* of level three.

CGAL::HalfedgeDS_const_decorator<HDS> page [863](#)

Example

The following program fragment illustrates the implementation of the Euler operator *split_vertex()* for a simplified polyhedron class.

```
template <class Traits>
namespace CGAL {
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        Halfedge_handle split_vertex( Halfedge_handle h, Halfedge_handle g) {
            HalfedgeDS_decorator<HDS> D(hds);
            // Stricter preconditions than for HalfedgeDS only.
            CGAL_precondition( D.get_vertex(h) == D.get_vertex(g));
            CGAL_precondition( h != g);
            return D.split_vertex( h, g);
        }
    };
}
```

CGAL::HalfedgeDS_default<Traits,HalfedgeDSItems,Alloc>

Definition

```
template < class Traits,
           class HalfedgeDSItems = CGAL::HalfedgeDS_items_2,
           class Alloc = CGAL_ALLOCATOR(int)>
class HalfedgeDS_default;
```

The class *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. The second template parameter *HalfedgeDSItems* has a default argument *CGAL::HalfedgeDS_items_2*. The third template parameter *Alloc* uses the CGAL default allocator as default setting. *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> is a list-based representation with bidirectional iterators that supports removal.

```
#include <CGAL/HalfedgeDS_default.h>
```

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> page [847](#)

Types

```
typedef bidirectional_iterator_tag    iterator_category;
typedef CGAL::Tag_true                Supports_removal;
```

Implementation

Currently, *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> is derived from *CGAL::HalfedgeDS_list*<Traits>. The copy constructor and the assignment operator need $O(n)$ time with n the total number of vertices, halfedges, and faces. The former suboptimal implementation with an $O(n \log n)$ runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

Due to a workaround for the flag *CGAL_CFG_NO_TMPL_IN_TMPL_PARAM*, a halfedge data structure cannot be instantiated directly. For the *HalfedgeDS_default*<Traits,HalfedgeDSItems,Alloc> a macro simplifies its direct use. However, when using a halfedge data structure as an argument for another class template, the class template name *HalfedgeDS_default* must be used, not the macro.

```

// The macro definition.
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    #define CGAL_HALFEDGE_DS_DEFAULT ::CGAL::HalfedgeDS_default
#else
    #define CGAL_HALFEDGE_DS_DEFAULT ::CGAL::HalfedgeDS_default::HDS
#endif

// The direct instantiation of the default HalfedgeDS given a Traits class.
typedef CGAL_HALFEDGE_DS_DEFAULT<Traits> HDS;

```

CGAL::HalfedgeDS_face_base<Refs>

Definition

The class *HalfedgeDS_face_base<Refs>* is a model of the *HalfedgeDSFace* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS_face_base<Refs>* has three parameters with some defaults that allow to select various flavors of faces. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

```
template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_face_base;
```

```
template <class Refs, class T, class Plane>
class HalfedgeDS_face_base;
```

HalfedgeDS_face_base<Refs> defines a face including a reference to an incident halfedge.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_false> is a face without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own faces. See also *CGAL::HalfedgeDS_face_min_base<Refs>*.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_true,Plane> is a face with a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems_3* concept.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_false,Plane> is a face without a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems_3* concept.

```
#include <CGAL/HalfedgeDS_face_base.h>
```

Is Model for the Concepts

CGAL::HalfedgeDS_halfedge_base<Refs>

Definition

The class *HalfedgeDS_halfedge_base*<Refs> is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. The full declaration states four template parameters:

```
template < class Refs,
           class Tag_prev = CGAL::Tag_true,
           class Tag_vertex = CGAL::Tag_true,
           class Tag_face = CGAL::Tag_true>
class HalfedgeDS_halfedge_base;
```

If *Tag_prev* \equiv *CGAL::Tag_true* a reference to the previous halfedge is supported.

If *Tag_vertex* \equiv *CGAL::Tag_true* an incident vertex is supported.

If *Tag_face* \equiv *CGAL::Tag_true* an incident face is supported.

In all cases, a reference to the next halfedge and to the opposite halfedge is supported.

```
#include <CGAL/HalfedgeDS_halfedge_base.h>
```

Is Model for the Concepts

CGAL::HalfedgeDS_items_2

Definition

The class *HalfedgeDS_items_2* is a model of the *HalfedgeDSItems* concept. It uses the default types for vertices, halfedges, and faces that declare all incidences supported by a *HalfedgeDS*. The vertex also contains a point of type *Traits::Point_2*, where *Traits* is the template argument of the corresponding *HalfedgeDS*.

```
#include <CGAL/HalfedgeDS_items_2.h>
```

Is Model for the Concepts

HalfedgeDSItems page [859](#)

See Also

CGAL::HalfedgeDS_min_items page [885](#)

CGAL::HalfedgeDS_halfedge_base<*Refs*> page [877](#)
CGAL::HalfedgeDS_face_base<*Refs*> page [874](#)

Example

The following example shows the canonical implementation of the *HalfedgeDS_items_2* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_2 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, Tag_true, Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_base< Refs> Face;
    };
};
```

The following example shows a class definition for a new items class derived from the *HalfedgeDS_items_2* class. It replaces the *Face_wrapper* with a new definition of a face that contains a member variable for color. The new face makes use of the face base class provided in the library.

```

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

```

CGAL::HalfedgeDS_items_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_items_decorator.h>
```

```

default constructor.

Access Functions

<i>Halfedge_handle</i>	<i>D.get_vertex_halfedge(Vertex_handle v)</i>	returns the incident halfedge of <i>v</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	-------------------------------------------------	------------------------------------------------------------------------------------------------

<i>Vertex_handle</i>	<i>D.get_vertex(Halfedge_handle h)</i>	returns the incident vertex of <i>h</i> if supported, <i>Vertex_handle()</i> otherwise.
----------------------	-----------------------------------------	--------------------------------------------------------------------------------------------

<i>Halfedge_handle</i>	<i>D.get_prev(Halfedge_handle h)</i>	returns the previous halfedge of <i>h</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	----------------------------------------	---------------------------------------------------------------------------------------------

<i>Halfedge_handle</i> <i>D.find_prev(Halfedge_handle h)</i>	returns the previous halfedge of <i>h</i> . Uses the <i>prev()</i> method if supported or performs a search around the face using <i>next()</i> .
---------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------

<i>Halfedge_handle</i>	<i>D.find_prev_around_vertex(Halfedge_handle h)</i> returns the previous halfedge of <i>h</i> . Uses the <i>prev()</i> method if supported or performs a search around the vertex using <i>next()</i> .
------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>Face_handle</i>	<i>D.get_face(Halfedge_handle h)</i>	returns the incident face of <i>h</i> if supported, <i>Face_handle()</i> otherwise.
--------------------	----------------------------------------	----------------------------------------------------------------------------------------

<i>Halfedge_handle</i>	<i>D.get_face_halfedge(Face_handle f)</i>	returns the incident halfedge of <i>f</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	--------------------------------------------	---------------------------------------------------------------------------------------------

Corresponding member functions for *const_handle*'s are provided as well.

Modifying Functions (Composed)

<i>void</i>	<i>D.close_tip(Halfedge_handle h)</i>	makes <i>h->opposite()</i> the successor of <i>h</i> .
-------------	----------------------------------------	-----------------------------------------------------------

<i>void</i>	<i>D.close_tip(Halfedge_handle h, Vertex_handle v)</i> makes <i>h->opposite()</i> the successor of <i>h</i> and sets the incident vertex of <i>h</i> to <i>v</i> .
-------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<code>void</code>	<code>D.insert_tip(Halfedge_handle h, Halfedge_handle v)</code>
	<p>inserts the tip of the edge h into the halfedges around the vertex pointed to by v. Halfedge $h \rightarrow \text{opposite}()$ is the new successor of v and $h \rightarrow \text{next}()$ will be set to $v \rightarrow \text{next}()$. The vertex of h will be set to the vertex v refers to if vertices are supported.</p>

<i>void</i>	<i>D.remove_tip(Halfedge_handle h)</i>	removes the edge <i>h->next()->opposite()</i> from the halfedge circle around the vertex referred to by <i>h</i> . The new successor halfedge of <i>h</i> will be <i>h->next()->opposite()->next()</i> .
-------------	------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>void</i>	<i>D.insert_halfedge(Halfedge_handle h, Halfedge_handle f)</i>	inserts the halfedge <i>h</i> between <i>f</i> and <i>f->next()</i> . The face of <i>h</i> will be the one <i>f</i> refers to if faces are supported.
<i>void</i>	<i>D.remove_halfedge(Halfedge_handle h)</i>	removes edge <i>h->next()</i> from the halfedge circle around the face referred to by <i>h</i> . The new successor of <i>h</i> will be <i>h->next()->next()</i> .
<i>void</i>	<i>D.set_vertex_in_vertex_loop(Halfedge_handle h, Vertex_handle v)</i>	loops around the vertex incident to <i>h</i> and sets all vertex pointers to <i>v</i> . <i>Precondition: h != Halfedge_handle().</i>
<i>void</i>	<i>D.set_face_in_face_loop(Halfedge_handle h, Face_handle f)</i>	loops around the face incident to <i>h</i> and sets all face pointers to <i>f</i> . <i>Precondition: h != Halfedge_handle().</i>
<i>Halfedge_handle</i>	<i>D.flip_edge(Halfedge_handle h)</i>	performs an edge flip. It returns <i>h</i> after rotating the edge <i>h</i> one vertex in the direction of the face orientation. <i>Precondition: h != Halfedge_handle() and both incident faces of h are triangles.</i>

Modifying Functions (Primitives)

<i>void</i>	<i>D.set_vertex_halfedge(Vertex_handle v, Halfedge_handle g)</i>	sets the incident halfedge of <i>v</i> to <i>g</i> .
<i>void</i>	<i>D.set_vertex_halfedge(Halfedge_handle h)</i>	sets the incident halfedge of the vertex incident to <i>h</i> to <i>h</i> .
<i>void</i>	<i>D.set_vertex(Halfedge_handle h, Vertex_handle v)</i>	sets the incident vertex of <i>h</i> to <i>v</i> .
<i>void</i>	<i>D.set_prev(Halfedge_handle h, Halfedge_handle g)</i>	sets the previous link of <i>h</i> to <i>g</i> .
<i>void</i>	<i>D.set_face(Halfedge_handle h, Face_handle f)</i>	sets the incident face of <i>h</i> to <i>f</i> .
<i>void</i>	<i>D.set_face_halfedge(Face_handle f, Halfedge_handle g)</i>	sets the incident halfedge of <i>f</i> to <i>g</i> .
<i>void</i>	<i>D.set_face_halfedge(Halfedge_handle h)</i>	sets the incident halfedge of the face incident to <i>h</i> to <i>h</i> .

Example

The following program fragment illustrates how a refined halfedge class for a polyhedron can make use of the *find_prev()* member function to implement a *prev()* member function that works regardless of whether the halfedge data structure *HDS* provides a *prev()* member function for its halfedges or not. In the case that not, the implementation given here runs in time proportional to the size of the incident face. For const-correctness a second implementation with signature *Halfedge_const_handle prev() const;* is needed.

Note also the use of the static member function *halfedge_handle()* of the halfedge data structure. It converts a pointer to the halfedge into a halfedge handle. This conversion encapsulates possible adjustments for hidden data members in the true halfedge type, such as linked-list pointers.

```
struct Polyhedron_halfedge {
    // ...
    Halfedge_handle prev() {
        CGAL::HalfedgeDS_items_decorator<HDS> decorator;
        return decorator.find_prev( HDS::halfedge_handle(this));
    }
};
```

CGAL::HalfedgeDS_min_items

Definition

The class *HalfedgeDS_min_items* is a model of the *HalfedgeDSItems* concept. It defines types for vertices, halfedges, and faces that declare the minimal required incidences for a *HalfedgeDS*, which are the *next()* and the *opposite()* member function for halfedges.

```
#include <CGAL/HalfedgeDS_min_items.h>
```

Is Model for the Concepts

 CGAL::HalfedgeDS_halfedge_min_base<Refs> page 878
 CGAL::HalfedgeDS_face_min_base<Refs> page 876

Example

The following example shows the canonical implementation of the *CGAL::HalfedgeDS_min_items* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>    Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>      Face;
    };
};
```

CGAL::HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc>

Definition

The class *HalfedgeDS_list*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. *HalfedgeDS_list*<Traits,HalfedgeDSItems,Alloc> is a list-based representation with bidirectional iterators that supports removal.

```
#include <CGAL/HalfedgeDS_list.h>
```

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> page [847](#)

Types

```
typedef bidirectional_iterator_tag    iterator_category;
typedef CGAL::Tag_true               Supports_removal;
```

Operations

Besides operations required from the concept *HalfedgeDS*<Traits,Items,Alloc>, this class supports additionally:

```
void    hds.vertices_splice( Vertex_iterator target, Self &source, Vertex_iterator first, Vertex_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

Precondition: *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

```
void    hds.halfedges_splice( Halfedge_iterator target,
                             Self &source,
                             Halfedge_iterator first,
                             Halfedge_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

Precondition: *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

```
void    hds.faces_splice( Face_iterator target, Self &source, Face_iterator first, Face_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

Precondition: *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

Implementation

HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc> uses internally the *CGAL::In_place_list* container class. The copy constructor and the assignment operator need $O(n)$ time with n the total number of vertices, halfedges, and faces. The former suboptimal implementation with an $O(n \log n)$ runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

CGAL_ALLOCATOR(int) is used as default argument for the *Alloc* template parameter.

CGAL::HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>

Definition

The class *HalfedgeDS_vector*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. *HalfedgeDS_vector*<Traits,HalfedgeDSItems,Alloc> is a vector-based representation with random access iterators that does not support removal.

```
#include <CGAL/HalfedgeDS_vector.h>
```

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> page [847](#)

Types

```
typedef random_access_iterator_tag    iterator_category;
typedef CGAL::Tag_false               Supports_removal;
```

Implementation

HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc> uses internally the STL *std::vector* container class. We require that we can create a *std::vector::iterator* from a pointer. If this will not be true any longer for any major STL distribution we might switch to an internal implementation of a vector.

The capacity is restricted to the reserved size. Allocations are not possible beyond the capacity without calling reserve again. All handles and iterators are invalidated upon a reserve call that increases the capacity.

CGAL_ALLOCATOR(int) is used as default argument for the *Alloc* template parameter.

CGAL::HalfedgeDS_vertex_base<Refs>

Definition

The class *HalfedgeDS_vertex_base<Refs>* is a model of the *HalfedgeDSVertex* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS_vertex_base<Refs>* has three parameters with some defaults that allow to select various flavors of vertices. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

```
template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_vertex_base;
```

```
template <class Refs, class T, class Point>
class HalfedgeDS_vertex_base;
```

HalfedgeDS_vertex_base<Refs> defines a vertex including a reference to an incident halfedge.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_false> is a vertex without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own vertex implementations. See also *CGAL::HalfedgeDS_vertex_min_base<Refs>*.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_true,Point> is a vertex with a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems_3* concept.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_false,Point> is a vertex without a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems_3* concept.

```
#include <CGAL/HalfedgeDS_vertex_base.h>
```

Polygon and Polyhedron Operations

Chapter 12

2D Regularized Boolean Set-Operations

Efi Fogel, Ron Wein, Baruch Zukerman, and Dan Halperin

12.1 Introduction

Figure 12.1: Examples of Boolean set-operations on general polygons.

This package consists of the implementation of Boolean set-operations on point sets bounded by x -monotone curves¹ in 2-dimensional Euclidean space. In particular, it contains the implementation of *regularized* Boolean set-operations, intersection predicates, and point containment predicates. Figure 12.1 shows simple examples of such operations.

A regularized Boolean set-operation op^* can be obtained by first taking the interior of the resultant point set of an *ordinary* Boolean set-operation ($P \text{ op } Q$) and then by taking the closure [Hof04]. That is, $P \text{ op}^* Q = \text{closure}(\text{interior}(P \text{ op } Q))$. Regularized Boolean set-operations appear in Constructive Solid Geometry (CSG), because regular sets are closed under regularized Boolean set-operations, and because regularization eliminates lower dimensional features, namely isolated vertices and antennas, thus simplifying and restricting the representation to physically meaningful solids. Our package provides regularized operations on polygons and general polygons, where the edges of a general polygon may be general x -monotone curves, rather than being simple line segments. Ordinary Boolean set-operations, which distinguish between the interior and the boundary of a polygon, are not implemented within this package. The *Nef_2* package supports these operations for (linear) polygons; see Chapter 13.

¹A continuous planar curve C is *x-monotone* if every vertical line intersects it at most once. We also allow vertical line segments, which are considered *weakly x-monotone*.

In the rest of this chapter we use — unless otherwise stated — the traditional notation to designate regularized operations; e.g., $P \cap Q$ means the *regularized* intersection of P and Q .

A polygon P is said to be *simple* (or Jordan) if the only points of the plane belonging to two polygon edges of P are the polygon vertices of P . Namely, the polygon edges are pairwise disjoint in their interior. Such a polygon has a well-defined interior and exterior and is topologically equivalent to a disk. A polygon in our context must be simple and its vertices must be ordered in a counterclockwise direction around the interior of the polygon.

The counterclockwise cyclic sequence of alternating polygon edges and polygon vertices is referred to as the polygon *boundary*. A polygon whose boundary contains the same vertex twice or more is connected and simple but not necessarily strictly simple, such as the polygon depicted on the right. We extend the notion of a polygon to a point set in \mathbb{R}^2 that has a topology of a polygon and its boundary edges must map to x -monotone curves, and refer to it as a *general polygon*. We sometimes use the term *polygon* instead of general polygon for simplicity hereafter.

Our package supports the following Boolean set-operations on two point sets P and Q that are comprised of general polygons:

Intersection computes the intersection $R = P \cap Q$.

Join computes the union $R = P \cup Q$.

Difference computes the difference $R = P \setminus Q$.

Symmetric Difference computes the symmetric difference $P = P \oplus Q = (P \setminus Q) \cup (Q \setminus P)$.

Complement computes the complement $R = \overline{P}$.

Intersection predicate tests whether the two sets P and Q overlap, distinguishing three possible scenarios: (i) the two sets intersect on their interior (that is, their regularized intersection is not empty $P \cap Q \neq \emptyset$); (ii) the boundaries of two sets intersect but their interiors are disjoint; namely they have a finite number of common points or even share a boundary curve (still in this case $P \cap Q = \emptyset$); and (iii) the two sets are disjoint.

In general, the set R , resulting from a regularized Boolean set-operation, is considered as being a closed point-set.

In the rest of this chapter we review the Boolean set-operations package in more depth. In Section 12.2 we focus on Boolean set-operations on linear polygons, introducing the notion of polygons with holes and of a general polygon set. Section 12.3 introduces general polygons. We first discuss polygons whose edges are either line segments or circular arcs and then explain how to construct and use general polygons whose edges can be arbitrary x -monotone curves.

12.2 Boolean Set-Operations on Linear Polygons

The basic library of CGAL includes the `Polygon_2<Kernel, Container>` class-template that represents a linear polygon in the plane. The polygon is represented by its vertices stored in a container of objects of type `Kernel::Point_2`. The polygon edges are line segments (`Kernel::Segment_2` objects) between adjacent points in the container. By default, the `Container` is a vector of `Kernel::Point_2` objects.

The following function demonstrates how to use the basic access functions of the `Polygon_2` class. It accepts a polygon P and prints it in a readable format:

```

template<class Kernel, class Container>
void print_polygon (const CGAL::Polygon_2<Kernel, Container>& P)
{
    typename CGAL::Polygon_2<Kernel, Container>::Vertex_const_iterator vit;

    std::cout << "[ " << P.size() << " vertices:";
    for (vit = P.vertices_begin(); vit != P.vertices_end(); ++vit)
        std::cout << " (" << *vit << ')';
    std::cout << " ]" << std::endl;
}

```

In this section we use the term *polygon* to indicate a *Polygon_2* instance, namely, a polygon having linear edges. General polygons are only discussed in Section 12.3.

The basic components of our package are the free (global) functions *complement()* that accepts a single *Polygon_2* object, and *intersection()*, *join()*,² *difference()*, *symmetric_difference()* and the predicate *do_intersect()* that accept two *Polygon_2* objects as their input. We explain how these functions should be used through several examples in the following sections.

A Simple Example

Testing whether two polygons intersect results with a Boolean value, and does not require any additional data beyond the provision of the two input polygons. The example listed below tests whether the two triangles depicted on the right intersect. It uses, as do the other example programs in this chapter, the auxiliary header file *bso_rational_nt.h*, which defines the type *Number_type* as GMP's rational number-type (*CGAL::Gmpq*), or as the number type *Quotient<MP_Float>* that is included in the support library of CGAL, based on whether the GMP library is installed or not. It also uses the function *print_polygon.h* listed above, which is located in the header file *print_utils.h*.

```

//! \file examples/Boolean_set_operations_2/ex_do_intersect.C
// Determining whether two triangles intersect.

```

```

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Boolean_set_operations_2.h>

typedef CGAL::Cartesian<Number_type>          Kernel;
typedef Kernel::Point_2                       Point_2;
typedef CGAL::Polygon_2<Kernel>               Polygon_2;

#include "print_utils.h"

int main ()
{
    Polygon_2 P;
    P.push_back (Point_2 (-1,1));
    P.push_back (Point_2 (0,-1));
    P.push_back (Point_2 (1,1));
    std::cout << "P = "; print_polygon (P);

    Polygon_2 Q;
    Q.push_back (Point_2 (-1,-1));
    Q.push_back (Point_2 (1,-1));

```

²The function that computes the union of two polygons is called *join()*, since the word *union* is reserved in C++.

```

Q.push_back(Point_2 (0,1));
std::cout << "Q = "; print_polygon (Q);

if ((CGAL::do_intersect (P, Q)))
    std::cout << "The two polygons intersect in their interior." << std::endl;
else
    std::cout << "The two polygons do not intersect." << std::endl;

return 0;
}

```

12.2.1 Polygons with Holes

Figure 12.2: Operations on strictly simple polygons. (a) The union of two polygons, resulting in a point set whose outer boundary is defined by a simple polygon and contains a polygonal hole in its interior. (b) The intersection (darkly shaded) of two polygons (lightly shaded), resulting in two disjoint polygons. (c) The complement (darkly shaded) of a strictly simple polygon (lightly shaded).

In many cases a binary operation that operates on two strictly simple polygons that have no holes may result in a set of polygon that contains holes in their interior (see Figure 12.2.1 (a)), or a set of disjoint polygons (see Figure 12.2.1 (b)); a similar set may result from the union, or the symmetric difference, of two disjoint polygons). Moreover, the complement of a simple polygon is an unbounded set that contains a hole; see Figure 12.2.1 (c).

Regular sets are closed under regularized Boolean set-operations. These operations accept as input, and may result as output, polygons with holes. A *polygon with holes* represents a point set that may be bounded or unbounded. In case of a bounded set, its *outer boundary* is represented as a simple (but not necessarily strictly simple) polygon, whose vertices are oriented in a counterclockwise order around the interior of the set. In addition, the set may contain *holes*, where each hole is represented as a strictly simple polygon, whose vertices are oriented in a clockwise order around the interior of the hole. Note that an unbounded polygon without holes spans the entire plane. Vertices of holes may coincide with vertices of the boundary; see below for an example.

A point set represented by a polygon with holes is considered to be closed. Therefore, the boundaries of the holes are parts of the set (and not part of the holes). The exact definition of the obtained polygon with holes as a result of a Boolean set-operation or a sequence of such operations is closely related to the definition of regularized Boolean set-operations, being the closure of the interior of the corresponding ordinary operation as explained next.

Consider, for example, the regular set depicted on the right, which is the result of the union of three small triangles translated appropriately. Alternatively, the same set can be reached by taking the difference between a large triangle and a small upside-down triangle. In general, there are many ways to arrive at a particular point set. However, the set of polygons with holes obtained through the application of any sequence of operations is unique. The set depicted on the right is represented as a single polygon having a triangular outer boundary with a single triangular hole in its interior — and not as three triangles that have no holes at all. As a general rule, if two point sets are connected, then they belong to the same polygon with holes.

The class template *Polygon_with_holes_2*<Kernel,Container> represents polygons with holes as described above, where the outer boundary and the hole boundaries are realized as *Polygon_2*<Kernel,Container> objects. Given an instance *P* of the *Polygon_with_holes_2* class, you can use the predicate *is_unbounded*() to check whether *P* is a unbounded set. If it is bounded, you can obtain the counterclockwise-oriented polygon that represents its outer boundary through the member function *outer_boundary*(). You can also traverse the holes of *P* through *holes_begin*() and *holes_end*(). The two functions return iterators of the nested type *Polygon_with_holes_2::Hole_const_iterator* that defines the valid range of *P*'s holes. The value type of this iterator is *Polygon_2*.

The following function demonstrates how to traverse a polygon with holes. It accepts a *Polygon_with_holes_2* object and uses the auxiliary function *print_polygon*() to prints all its components in a readable format:

```
template<class Kernel, class Container>
void print_polygon_with_holes(const CGAL::Polygon_with_holes_2<Kernel, Container> & pwh)
{
    if (! pwh.is_unbounded()) {
        std::cout << "{ Outer boundary = ";
        print_polygon (pwh.outer_boundary());
    }
    else
        std::cout << "{ Unbounded polygon." << std::endl;

    typename CGAL::Polygon_with_holes_2<Kernel,Container>::Holes_const_iterator hit;
    unsigned int k = 1;

    std::cout << " " << pwh.number_of_holes() << " holes:" << std::endl;
    for (hit = pwh.holes_begin(); hit != pwh.holes_end(); ++hit, ++k) {
        std::cout << "    Hole #" << k << " = ";
        print_polygon (*hit);
    }
    std::cout << " }" << std::endl;
}
```

The simple versions of the free functions mentioned therefore accept two *Polygon_2* object *P* and *Q* as their input, while their output is given using polygon with holes instances:

- The complement of a simple polygon *P* is always an unbounded set with a single polygonal hole. The function *complement(P)* therefore returns a polygon-with-holes object that represents the complement of *P*.
- The union of two polygons *P* and *Q* is always a single connected set, unless of course the two input polygons are completely disjoint. In the latter case $P \cup Q$ trivially consists of the two input polygons. The free function *join(P, Q, R)* therefore returns a Boolean value indicating whether $P \cap Q \neq \emptyset$. If the two polygons are not disjoint, it assigns the a polygon with holes object *R* (which it accepts by reference) with the union of the regularized union operation $P \cup Q$.

- The other three functions, namely *intersection(P, Q, oi)*, *difference(P, Q, oi)* and *symmetric_difference(P, Q, oi)*, all have a similar interface. As the result of these operation may consist of several disconnected components, they all accept an output iterator *oi*, whose value type is *Polygon_with_holes_2*, and add the output polygons to its associated container.

Example — Joining and Intersecting Simple Polygons

The following example demonstrates the usage of the free functions *join()* and *intersect()* for computing the union and the intersection of the two simple polygons depicted in Figure 12.2.1 (b). The example uses the auxiliary function *print_polygon_with_holes()* listed above, which is located in the header file *print_utils.h* under the examples folder.

```

//! \file examples/Boolean_set_operations_2/ex_simple_join_intersect.C
// Computing the union and the intersection of two simple polygons.

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Boolean_set_operations_2.h>
#include <list>

typedef CGAL::Cartesian<Number_type>          Kernel;
typedef Kernel::Point_2                       Point_2;
typedef CGAL::Polygon_2<Kernel>               Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>    Polygon_with_holes_2;
typedef std::list<Polygon_with_holes_2>       Pwh_list_2;

#include "print_utils.h"

int main ()
{
    // Construct the two input polygons.
    Polygon_2 P;
    P.push_back (Point_2 (0, 0));
    P.push_back (Point_2 (5, 0));
    P.push_back (Point_2 (3.5, 1.5));
    P.push_back (Point_2 (2.5, 0.5));
    P.push_back (Point_2 (1.5, 1.5));

    std::cout << "P = "; print_polygon (P);

    Polygon_2 Q;
    Q.push_back (Point_2 (0, 2));
    Q.push_back (Point_2 (1.5, 0.5));
    Q.push_back (Point_2 (2.5, 1.5));
    Q.push_back (Point_2 (3.5, 0.5));
    Q.push_back (Point_2 (5, 2));

    std::cout << "Q = "; print_polygon (Q);

    // Compute the union of P and Q.
    Polygon_with_holes_2 unionR;

```

```

if (CGAL::join (P, Q, unionR)) {
    std::cout << "The union: ";
    print_polygon_with_holes (unionR);
} else
    std::cout << "P and Q are disjoint and their union is trivial."
                << std::endl;
std::cout << std::endl;

// Compute the intersection of P and Q.
Pwh_list_2          intR;
Pwh_list_2::const_iterator it;

CGAL::intersection (P, Q, std::back_inserter(intR));

std::cout << "The intersection:" << std::endl;
for (it = intR.begin(); it != intR.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
}

return 0;
}

```

Operations on Polygons with Holes

Having introduced polygons with holes and explained how the free functions output such objects, it is only natural to perform operations on sets that are represented as polygon with holes, rather than simple polygons. Indeed, the Boolean set-operations package provides overridden free functions *complement()*, *intersection()*, *join()*, *difference()*, *symmetric_difference()* and *do_intersect()* that accept *General_polygon_with_holes_2* objects as their input. The prototypes of most functions is the same as of their simpler counterparts that operate on simple polygons. The only exception is *complement(P, oi)*, which outputs a range of polygons with holes that represents the complement of the polygon with holes *P*.

The following example demonstrates how to compute the symmetric difference between two sets that contain holes. Each set is a rectangle that contains a rectangular hole in its interior, such that the symmetric difference between the two sets is a single polygon that contains of five holes:

```

//! \file examples/Boolean_set_operations_2/ex_symmetric_difference.C
// Computing the symmetric difference of two polygons with holes.

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Boolean_set_operations_2.h>
#include <list>

typedef CGAL::Cartesian<Number_type>          Kernel;
typedef Kernel::Point_2                       Point_2;
typedef CGAL::Polygon_2<Kernel>              Polygon_2;

```

```

typedef CGAL::Polygon_with_holes_2<Kernel>          Polygon_with_holes_2;
typedef std::list<Polygon_with_holes_2>             Pwh_list_2;

#include "print_utils.h"

int main ()
{
    // Construct P - a bounded rectangle that contains a rectangular hole.
    Polygon_2 outP;
    Polygon_2 holesP[1];

    outP.push_back (Point_2 (-3, -5)); outP.push_back (Point_2 (3, -5));
    outP.push_back (Point_2 (3, 5));   outP.push_back (Point_2 (-3, 5));
    holesP[0].push_back (Point_2 (-1, -3));
    holesP[0].push_back (Point_2 (-1, 3));
    holesP[0].push_back (Point_2 (1, 3));
    holesP[0].push_back (Point_2 (1, -3));

    Polygon_with_holes_2 P (outP, holesP, holesP + 1);
    std::cout << "P = "; print_polygon_with_holes (P);

    // Construct Q - a bounded rectangle that contains a rectangular hole.
    Polygon_2 outQ;
    Polygon_2 holesQ[1];

    outQ.push_back (Point_2 (-5, -3)); outQ.push_back (Point_2 (5, -3));
    outQ.push_back (Point_2 (5, 3));   outQ.push_back (Point_2 (-5, 3));
    holesQ[0].push_back (Point_2 (-3, -1));
    holesQ[0].push_back (Point_2 (-3, 1));
    holesQ[0].push_back (Point_2 (3, 1));
    holesQ[0].push_back (Point_2 (3, -1));

    Polygon_with_holes_2 Q (outQ, holesQ, holesQ + 1);
    std::cout << "Q = "; print_polygon_with_holes (Q);

    // Compute the symmetric difference of P and Q.
    Pwh_list_2 symmR;
    Pwh_list_2::const_iterator it;

    CGAL::symmetric_difference (P, Q, std::back_inserter(symmR));

    std::cout << "The symmetric difference:" << std::endl;
    for (it = symmR.begin(); it != symmR.end(); ++it) {
        std::cout << "--> ";
        print_polygon_with_holes (*it);
    }

    return 0;
}

```

12.2.2 Operating on Polygon Sets

We argue that the result of a regularized operations on two polygons (or polygons with holes) P and Q is typically a collection of several disconnected polygons with holes. It is only natural to represent such a collection in terms of a class, making it possible to operate on the set resulting from computing, for example, $P \setminus Q$.

A central component in the Boolean set-operations package is the *Polygon_set_2*<*Kernel*, *Container*> class-template. An instance of this class represents a point set formed by the collection of several disconnected polygons with holes. It employs the *Arrangement_2* class to represent this point set in the plane as a planar arrangement; see Chapter 17.

An instance S of a *Polygon_set_2* class usually represents the result of a sequence of operations that were applied on some input polygons. The representation of S is unique, regardless of the particular sequence of operations that were applied in order to arrive at it.

In addition, a polygon-set object can be constructed from a single polygon object or from a polygon-with-holes object. Once constructed, it is possible to insert new polygons (or polygons with holes) into the set using the *insert()* method, as long as the inserted polygons and the existing polygons in the set are disjoint. The *Polygon_set_2* class also provides access functions for accessing the polygons with holes it contains, and a few queries. The most important query is *S.oriented_side(q)*, which determined whether the query point q is contained in the interior of the set S , lies on the boundary of the set, or neither.

The *General_polygon_set_2* class defines the predicate *do_intersect()* and the methods *complement()*, *intersection()*, *join()*, *difference()* and *symmetric_difference()* as member functions. The operands to these functions may be simple polygons (*Polygon_2* object), polygons with holes (*General_polygon_with_holes_2* objects), or polygon sets (*General_polygon_set_2* objects). Thus, each of the function mentioned above is actually realized by a set overriding member functions.

Member functions of the *General_polygon_set_2* that perform Boolean set-operations come in two flavors: for example, *S.join(P, Q)* computes the union of P and Q and assigned the result to S , while *S.join(P)* performs the operation $S \leftarrow S \cup P$. Similarly, *S.complement(P)* sets S to be the complement of P , while *S.complement()* simply negates the set S .

A Sequence of Set Operations

The free functions reviewed in Section 12.2.1 serve as a wrapper for the polygon-set class, and are only provided for convenience. A typical such function constructs a pair of *General_polygon_set_2* objects, invokes the appropriate method to apply the desired Boolean operation, and transforms the resulting polygon set to the required output format. Thus, when several operations are performed in a sequence, it is much more efficient to use the member functions of the *General_polygon_set_2* type directly, as the extraction of the polygons from the internal representation for some operation, and the reconstruction of the internal representation for the succeeding operation could be time consuming.

The next example performs a sequence of three Boolean set-operations. First, it computes the union of two simple polygons depicted in Figure 12.2.1 (a). It then computes the complement of the result of the union operation. Finally, it computes the intersection of the result of the complement operation with a rectangle, confining the final result to the area of the rectangle. The resulting set S is comprised of two components: a polygon with a hole, and a simple polygon contained in the interior of this hole.

```
/// \file examples/Boolean_set_operations_2/ex_sequence.C
// Performing a sequence of Boolean set-operations.
```

```

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/Polygon_with_holes_2.h>
#include <CGAL/Polygon_set_2.h>

#include <list>

typedef CGAL::Cartesian<Number_type>      Kernel;
typedef Kernel::Point_2                   Point_2;
typedef CGAL::Polygon_2<Kernel>           Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;
typedef CGAL::Polygon_set_2<Kernel>       Polygon_set_2;

#include "print_utils.h"

int main ()
{
    // Construct the two initial polygons and the clipping rectangle.
    Polygon_2 P;
    P.push_back (Point_2 (0, 1));
    P.push_back (Point_2 (2, 0));
    P.push_back (Point_2 (1, 1));
    P.push_back (Point_2 (2, 2));

    Polygon_2 Q;
    Q.push_back (Point_2 (3, 1));
    Q.push_back (Point_2 (1, 2));
    Q.push_back (Point_2 (2, 1));
    Q.push_back (Point_2 (1, 0));

    Polygon_2 rect;
    rect.push_back (Point_2 (0, 0));
    rect.push_back (Point_2 (3, 0));
    rect.push_back (Point_2 (3, 2));
    rect.push_back (Point_2 (0, 2));

    // Perform a sequence of operations.
    Polygon_set_2 S;
    S.insert (P);
    S.join (Q);           // Compute the union of P and Q.
    S.complement();       // Compute the complement.
    S.intersection (rect); // Intersect with the clipping rectangle.

    // Print the result.
    std::list<Polygon_with_holes_2> res;
    std::list<Polygon_with_holes_2>::const_iterator it;

    std::cout << "The result contains " << S.number_of_polygons_with_holes()
               << " components:" << std::endl;

    S.polygons_with_holes (std::back_inserter (res));
    for (it = res.begin(); it != res.end(); ++it) {
        std::cout << "--> ";
    }
}

```

```

    print_polygon_with_holes (*it);
}

return 0;
}

```

Inserting Non Intersecting Polygons

If you want to compute the union of a polygon P (P may be a simple polygon or a polygon-with-holes object) with a general-polygon set R , and store the result in R , you can construct a polygon set $S(P)$, and apply the *union* operation as follows:

```

General_polygon_2 S (P);
R.join (S);

```

As a matter of fact, you can apply the union operation directly:

```

R.join (P);

```

However, if you know that the polygon does not intersect any one of the polygons represented by R , you can use the more efficient method *insert()*:

```

R.insert (P);

```

As *insert()* assumes that $P \cap R = \emptyset$, it does not try to compute intersections between the boundaries of P and of R . This fact significantly speeds up the insertion process in comparison with the insertion of a non-disjoint polygon that intersects R .

The *insert()* function is also overloaded, so it can also accept a range of polygons. When a range of polygons are inserted into a polygon set S , all the polygons in the range and the polygons represented by S must be pairwise disjoint in their interiors.

12.2.3 Performing Aggregated Operations

There are a few options to compute the union of a set of polygons P_1, \dots, P_m . You can do it incrementally as follows. At each step compute the union of $S_{k-1} = \bigcup_{i=1}^{k-1} P_i$ with P_k and obtain S_k . Namely, if the polygon set is given as a pair of iterator $[begin, end)$, the following loop computes their union in S .

```

InputIterator iter = begin;
Polygon_set_2 S (*iter);

while (++iter != end) {
    S.join (*iter);
    ++iter;
}

```

A second option is to use a divide-and-conquer approach. You bisect the set of polygons into two sets. Compute the union of each set recursively and obtain the partial results in S_1 and S_2 , and finally, you compute the union $S_1 \cup S_2$. However, the union operation can be done more efficiently for sparse polygons, having a relatively small number of intersections, using a third option that simultaneously computes the union of all polygons. This is done by constructing a planar arrangement of all input polygons, utilizing the sweep-line algorithm, then extracting the result from the arrangement. Similarly, it is also possible to aggregately compute the intersection $\bigcap_{i=1}^m P_i$ of a set of input polygons.

Our package provides the free overloaded functions *join()* and *intersect()* that aggregately compute the union and the intersection of a range of input polygons. There is no restriction on the polygons in the range — naturally, they may intersect each other. The package provides the overloaded free function *do_intersect(begin, end)* that determines whether the polygons in the range defined by the two input iterators *[begin, end)* intersect.

The class *General_polygon_set_2* also provides equivalent member functions that aggregately operate on a range of input polygons or polygons with holes. When such a member function is called, the general polygons represented by the current object are considered operands as well. Thus, you can easily compute the union of our polygon range as follows:

```
Polygon_set_2 S;  
S.join (begin, end);
```

12.3 Boolean Set-Operations on General Polygons

In previous sections ordinary polygons were dealt with. Namely, closed point sets bounded by piecewise linear curves. The Boolean set-operations package allows a more general geometric mapping of the polygon edges. The operations provided by the package operate on point sets bounded by x -monotone segments of general curves (e.g., conic arcs and segments of polynomial functions). For example, the point set depicted on the right is general polygon bounded by two x -monotone circular arcs that correspond to the lower half and the upper half of a circle.

Using the topological terminology, a general polygon can represent any simply-connected point set whose boundary is a strictly simple curve. Such a polygon is a model of the *GeneralPolygon_2* concept. A model of this concept must fulfill the following requirements:

- A general polygon is constructible from a range of pairwise interior disjoint x -monotone curves c_1, \dots, c_n . The target point of the k th curve c_k and the source point of the next curve in the range (in a cyclic order) must coincide, such that this point defines the k th polygon vertex.
- It is possible to traverse the x -monotone curves that form the edges of a general polygon.

The concept *GeneralPolygonWithHoles_2* is defined in an analogous way to the definition of linear polygons with holes. A model of this concept represent a bounded or an unbounded set that may not be simply connected, and must provide the following operations:

- Construction for a general polygon that represent the outer boundary and a range of general polygons that represent the holes.
- Accessing the general polygons that represents the outer boundary (in case of a bounded set).

- Traversing the holes.

In Section 12.2 we introduce the classes *Polygon_2* and *Polygon_with_holes_2* that model the concepts *GeneralPolygon_2* and *GeneralPolygonWithHoles_2* respectively. In this section we introduce other models of these two concepts.

The central class-template *General_polygon_set_2<Traits>* is used to represent point sets that are comprised of a finite number of general polygons with holes that are pairwise disjoint, and provides various Boolean set-operations on such sets. It is parameterized by a *traits* class that defines the type of points used to represent polygon vertices and the type of *x*-monotone curves that represent the polygon edges. The traits class also provides primitive geometric operations that operate on objects of these types. An instantiated *General_polygon_set_2* class defines the nested types *General_polygon_set_2<Traits>::Polygon_2* and *General_polygon_set_2<Traits>::Polygon_with_holes_2*, which model the concepts *GeneralPolygon_2* and *GeneralPolygonWithHoles_2* respectively.

12.3.1 The Traits-Class Concepts

The traits class used to instantiate the *General_polygon_set_2* class template must model the concept *GeneralPolygonSetTraits_2*, and is tailored to handle a specific family of curves. The concept *GeneralPolygonSetTraits_2* refines the concept *ArrangementDirectionalXMonotoneTraits_2* specified next.

The concept *ArrangementDirectionalXMonotoneTraits_2* refines the concept *ArrangementXMonotoneTraits_2* (see Section 17.4.1 in the 2D Arrangements chapter). Thus, a model of this concept must define the type *X_monotone_curve_2*, which represents an *x*-monotone curve, and the type *Point_2*, which represents a planar point. Such a point may be an endpoint of an *x*-monotone curve or an intersection point between two curves. It must also provide various geometric predicates and operations on these types listed by the base concept, such as determining whether a point lies above or below an *x*-monotone curve, computing the intersections between two curves, etc. Note that the base concept does not assume that *x*-monotone curves are directed: an *x*-monotone curve is not required to have a designated *source* and *target*, it is only required to determine the left (lexicographically smaller) and the right (lexicographically larger) endpoints of a given curve.

The *ArrangementDirectionalXMonotoneTraits_2* concept treats its *x*-monotone curves as directed objects. It thus requires two additional operations on *x*-monotone curves:

- Given an *x*-monotone curve, compare its source and target points lexicographically.
- Given an *x*-monotone curve, construct its opposite curve (namely, swap its source and target points).

The traits classes *Arr_segment_traits_2*, *Arr_non_caching_segment_traits*, *Arr_circle_segment_traits_2*, *Arr_conic_traits_2* and *Arr_rational_arc_traits_2*, which are bundled in the *Arrangement_2* package and distributed with CGAL, are all models of the refined concept *ArrangementDirectionalXMonotoneTraits_2*.³

Just as with the case of computations using models of the *ArrangementXMonotoneTraits_2* concept, operations are robust only when exact arithmetic is used. When inexact arithmetic is used, (nearly) degenerate configurations may result in abnormal termination of the program or even incorrect results.

³The *Arr_polyline_traits_2* class is *not* a model of the, *ArrangementDirectionalXMonotoneTraits_2* concept, as the *x*-monotone curve it defines is always directed from left to right. Thus, an opposite curve cannot be constructed. However, it is not very useful to construct a polygon whose edges are polylines, as an ordinary polygon with linear edges can represent the same entity.

12.3.2 Operating on Polygons with Circular Arcs

Two traits classes are distributed with CGAL. The first one is named *Gps_segment_traits_2*, and it is used to perform Boolean set-operations on ordinary polygons and polygons with holes. In fact, the class *Polygon_set_2* introduced in Section 12.2.2 is a specialization of *General_polygon_set_2<Gps_segment_traits_2>*. This class defined its polygon and polygon with holes types, such that the usage of this traits class is encapsulated in the polygon-set class.

The other predefined traits class is named *Gps_circle_segment_traits_2<Kernel>* and is parameterized by a geometric CGAL kernel. By instantiating the *General_polygon_set_2* with this traits class, we obtain the representation of a polygon whose boundary may be comprised of line segments and circular arcs. The circle-segment traits class provides predicates and constructions on non-linear objects; yet, it uses only rational arithmetic and is very efficient as a consequence.

The following example uses the *Gps_circle_segment_traits_2* class to compute the union of four rectangles and four circles. Each circle is represented as a general polygon having two *x*-monotone circular arcs. The union is computed incrementally, resulting with a single polygon with a single hole, as depicted on the right. Note that as the four circles are disjoint, their union is computed with the *insert* method, while the union with the rectangles is computed with the *join* operator.

```

12.3.3 General Polygon Set Traits Adapter

The concept *GeneralPolygon_2* and its generic model *General_polygon_2<ArrDirectionalXMonotoneTraits>* facilitate the production of general-polygon set traits classes. A model of the concept *GeneralPolygon_2* represents a simple point-set in the plane bounded by *x*-monotone curves. As opposed to the plain *Traits::Polygon_2* type defined by any traits class, it must define the type *X_monotone_curve_2*, which represents an *x*-monotone curve of the point-set boundary. It must provide a constructor from a range of such curves, and a pair of methods, namely *curves_begin()* and *curves_end()*, that can be used to iterate over the point-set boundary curves.

The class-template *General_polygon_2<ArrDirectionalXMonotoneTraits>* models the concept *GeneralPolygon_2*. Its template parameter must be instantiated with a model of the concept *ArrangementDirectionalXMonotoneTraits_2* from which it obtains the *X_monotone_curve_2* type, and it uses the necessary operations on this type provided by such a model to maintain a container of directed curves of type *X_monotone_curve_2*, which represents the boundary of the general polygon.

The class-template *Gps_traits_2<ArrDirectionalXMonotoneTraits,GeneralPolygon>* models the concept *GeneralPolygonSetTraits_2*. Its implementation is rather simple, as it is derived from the instantiated template-parameter *ArrXMonotoneTraits_2* inheriting its necessary types and methods, and it exploits the methods provided by the instantiated parameter *GeneralPolygon* — a model of the concept *GeneralPolygon_2*. By default, the *GeneralPolygon* parameter is defined as *General_polygon_2<ArrangementDirectionalXMonotoneTraits_2>*

The code excerpt listed below defines a general-polygon set type that can be used to perform Boolean set-operations on point sets bounded by linear segments used by the *Arrangement_2* class by default. A model of the *GeneralPolygon_2* concept that represents a (linear) polygon bounded by curves of type *Arr_segment_2* is generated. The later is obtained from the instantiated parameter *Arr_segment_traits_2*, which defines *Arr_segment_2* to be its exposed type *X_monotone_curve_2*.

```

typedef CGAL::Gmpq                                     Number_type;
typedef CGAL::Cartesian<Number_type>                   Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>              Arr_traits_2;
typedef CGAL::General_polygon_2<Arr_traits_2>           General_polygon_2;
typedef CGAL::Gps_traits_2<Arr_traits_2,General_polygon_2> Traits_2;
typedef CGAL::General_polygon_set_2<Traits_2>          General_polygon_set_2;

```

Swapping the linear arrangement-traits *Arr_segment_traits_2* above with a traits class that handle conic arcs, such as *Arr_conic_traits_2*, results with the definition of a general-polygon set type that can be used to perform Boolean set-operations on point sets bounded by conic arcs of type *Arr_conic_2*. The next example computes the intersection of the two general polygons depicted on the right. One is an ellipse given by $x^2 + 9y^2 - 9 = 0$, and the other is bounded by the two parabolic arcs whose underlying parabola are given by $x^2 + 2y - 4 = 0$, and $x^2 - 2y - 4 = 0$. The code in the example adapts the traits model that handles conics included with the *Arrangement_2* package.

```

//! \file examples/Boolean_set_operations_2/ex_traits_adaptor.C
// Using the traits adaptor to generate a traits of conics.
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE

    CGAL::intersection (P, Q, std::back_inserter(res));

    std::copy (res.begin(), res.end(),          // export to standard output
               std::ostream_iterator<Polygon_with_holes_2>(std::cout, "\n"));
    std::cout << std::endl;

    return (0);
}

#endif

```

12.3.4 Example - Aggregated Operations

In Section [12.2.3](#) we describe how aggregated union and intersection operations can be applied to a collection of ordinary polygons or polygons with holes. Naturally, the aggregated operations can be applied also to collections of general polygons. As was the case with ordinary polygons, using aggregated operations is recommended when the number of intersections of the input polygons is of the same order of magnitude as the complexity of

the result. If this is not the case, computing the result incrementally may prove faster.

The next example computes the union of eight unit discs whose centers are placed a unit distance from the origin, as depicted to the right. The example also allows users to provide a different number of discs through the command line.

```

//! \file examples/Boolean_set_operations_2/ex_set_union.C
// Computing the union of a set of circles.

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>

    return 0;
}

```

2D Regularized Boolean Set-Operations Reference Manual

Efi Fogel, Ron Wein, Baruch Zukerman, and Dan Halperin

Introduction

This package consists of the implementation of Boolean set-operations on point sets bounded by x -monotone curves in 2-dimensional Euclidean space. In particular, it contains the implementation of regularized Boolean set-operations, intersection predicates, and point containment predicates.

CGAL::General_polygon_set_2<Traits>

Definition

An object of the *General_polygon_set_2<Traits>* class-template represents a point set in the plane bounded by x monotone curves. Points in the set lie on the boundary or on the positive side of the curves. This class template provides methods to apply regularized Boolean set-operations and few other utility methods. An *Arrangement_2* data structure is internally used to represent the point set.

The *Traits* template-parameter should be instantiated with a model of the concept *GeneralPolygonSetTraits_2*. The traits class defines the types of points, x -monotone curves, general polygons, and general polygons with holes, that is *Traits::Point_2*, *Traits::X_monotone_curve_2*, *Traits::Polygon_2*, and *Traits::Polygon_with_holes_2* respectively. *Traits::Point_2* must be the type of the endpoints of *Traits::X_monotone_curve_2*, and *Traits::X_monotone_curve_2* must be the type of the curves that comprise the boundaries of the general polygons. The traits class supports geometric operations on the types above. We sometimes use the term *polygon* instead of general polygon for simplicity hereafter.

The input and output of the Boolean set-operations methods consist of one or more general polygons, some of which may have holes. In particular, these methods operate on pairs of objects of type *General_polygon_set_2<Traits>*, or directly on objects of type *Traits::Polygon_2* or *Traits::Polygon_with_holes_2*. An object of type *Traits::Polygon_2* is a valid operand, only if it is strictly simple and its boundary is oriented counterclockwise. An object of type *Traits::Polygon_with_holes_2* is valid, only if its outer boundary is simple and oriented counterclockwise, and each one of its holes is a strictly simple polygon that oriented clockwise, contained inside its outer boundary, and they are all together pairwise disjoint, except perhaps at the vertices.

Types

<i>General_polygon_set_2<Traits>:: Traits_2</i>	the traits class in use.
<i>General_polygon_set_2<Traits>:: Polygon_2</i>	the general polygon type.
<i>General_polygon_set_2<Traits>:: Polygon_with_holes_2</i>	the general polygon with holes type.
<i>General_polygon_set_2<Traits>:: Size</i>	number of polygons with holes size type.
<i>General_polygon_set_2<Traits>:: Arrangement_2</i>	the arrangement type used internally.

Creation

<i>General_polygon_set_2<Traits> gps;</i>	constructs an empty set of polygons represented by an empty arrangement.
<i>General_polygon_set_2<Traits> gps(Self other);</i>	copy constructor.

<i>General_polygon_set_2</i> < <i>Traits</i> > <i>gps</i> (<i>Traits</i> & <i>traits</i>);	constructs an empty set of polygons that uses the given <i>traits</i> instance for performing the geometric operations.
<i>General_polygon_set_2</i> < <i>Traits</i> > <i>gps</i> (<i>Polygon_2</i> <i>pgn</i>);	constructs a set of polygons that consists of the single polygon <i>pgn</i> .
<i>General_polygon_set_2</i> < <i>Traits</i> > <i>gps</i> (<i>Polygon_with_holes_2</i> <i>pgn_with_holes</i>);	constructs a set of polygons that consists of the single polygon with holes <i>pgn_with_holes</i> .

Access Functions

<pre>template <class OutputIterator> OutputIterator gps.polygons_with_holes(OutputIterator out)</pre>		obtains the polygons with holes represented by <i>gps</i> .
<i>Size</i>	<i>gps.number_of_polygons_with_holes()</i>	returns the total number of general polygons represented by <i>gps</i> .
<i>bool</i>	<i>gps.is_empty()</i>	returns <i>true</i> if <i>gps</i> represents an empty set.
<i>bool</i>	<i>gps.is_plane()</i>	returns <i>true</i> if <i>gps</i> represents the entire plane.
<i>Traits</i> &	<i>gps.traits()</i>	obtains an instance of the traits. If the traits was passed as a parameter to the constructor of <i>gps</i> , it is returned. Otherwise, a newly created instance is returned.
<i>Arrangement_2</i>	<i>gps.arrangement()</i>	obtains the arrangement data structure that internally represents the general-polygon set.

Modifiers

<i>void</i>	<i>gps.clear()</i>	clears <i>gps</i> .
<i>void</i>	<i>gps.insert(Polygon_2 & pgn)</i>	<p>inserts <i>pgn</i> into <i>gps</i>.</p> <p><i>Precondition:</i> <i>pgn</i> and the point set represented by <i>gps</i> are disjoint. This precondition enables the use of very efficient insertion methods. Use the respective overloaded method that inserts a polygon of type <i>Polygon_with_holes_2</i>, if only a relaxed precondition can be guaranteed. If even the relaxed precondition cannot be guaranteed, use the <i>join</i> method.</p>

`void gps.insert(Polygon_with_holes_2 & pgn_with_holes)`

inserts *pgn_with_holes* into *gps*.

Precondition: *pgn_with_holes* does not intersect with the point set represented by *gps*, except maybe at the vertices. If this relaxed precondition cannot be guaranteed, use the *join* method.

`template <class InputIterator>`

`void gps.insert(InputIterator begin, InputIterator end)`

inserts the range of polygons (or polygons with holes) into *gps*. (The value type of the input iterator is used to distinguish between the two.)

Precondition: If the given range contains objects of type *Polygon_with_holes_2*, then these polygons and the point set represented by *gps* are pairwise disjoint, except maybe at the vertices. If the given range contains objects of type *Polygon_2*, then these polygons and the point set represented by *gps* are pairwise disjoint without any exceptions.

`template <class InputIterator1, class InputIterator2>`

`void gps.insert(InputIterator1 pgn_begin,
 InputIterator1 pgn_end,
 InputIterator2 pgn_with_holes_begin,
 InputIterator2 pgn_with_holes_end)`

inserts the two ranges of polygons and polygons with holes into *gps*.

Precondition: All polygons in the first range, all polygon with holes in the second range, and the point set represented by *gps* are pairwise disjoint, except maybe at the vertices

`void gps.complement()`

computes the complement of *gps*.

`void gps.complement(Polygon_set_2 other)`

computes the complement of *other*. *gps* is overridden by the result.

Univariate Operations

In the following univariate and bivariate methods the result is placed in *gps* after it is cleared.

`void gps.intersection(General_polygon_set_2 other)`

computes the intersection of *gps* and *other*.

`void gps.intersection(Polygon_2 pgn)`

computes the intersection of *gps* and *pgn*.

`void gps.intersection(Polygon_with_holes_2 pgn)`

computes the intersection of *gps* and *pgn*.

```
template <class InputIterator>
void    gps.intersection( InputIterator begin, InputIterator end)
```

computes the intersection of a collection of point sets. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
void    gps.intersection( InputIterator1 pgn_begin,
                          InputIterator1 pgn_end,
                          InputIterator2 pgn_with_holes_begin,
                          InputIterator2 pgn_with_holes_end)
```

computes the intersection of a collection of point sets. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

```
void    gps.join( General_polygon_set_2 other)
void    gps.join( Polygon_2 pgn)
void    gps.join( Polygon_with_holes_2 pgn)
```

computes the union of *gps* and *other*.
computes the union of *gps* and *pgn*.
computes the union of *gps* and *pgn*.

```
template <class InputIterator>
void    gps.join( InputIterator begin, InputIterator end)
```

computes the union of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
void    gps.join( InputIterator1 pgn_begin,
                  InputIterator1 pgn_end,
                  InputIterator2 pgn_with_holes_begin,
                  InputIterator2 pgn_with_holes_end)
```

computes the union of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

```
void    gps.difference( General_polygon_set_2 other)
```

computes the difference between *gps* and *other*.

```
void    gps.difference( Polygon_2 pgn)
void    gps.difference( Polygon_with_holes_2 pgn)
```

computes the difference between *gps* and *pgn*.
computes the difference between *gps* and *pgn*.

```
void    gps.symmetric_difference( General_polygon_set_2 other)
```

computes the symmetric difference between *gps* and *other*.

```
void    gps.symmetric_difference( Polygon_2 pgn)
```

computes the symmetric difference between *gps* and *pgn*.

```
void    gps.symmetric_difference( Polygon_with_holes_2 pgn)
```

computes the symmetric difference between *gps* and *pgn*.

```
template <class InputIterator>
```

```
void    gps.symmetric_difference( InputIterator begin, InputIterator end)
```

computes the symmetric difference (xor) of a collection of point sets. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
```

```
void    gps.symmetric_difference( InputIterator1 pgn_begin,
                                InputIterator1 pgn_end,
                                InputIterator2 pgn_with_holes_begin,
                                InputIterator2 pgn_with_holes_end)
```

computes the symmetric difference (xor) of a collection of point sets. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

Bivariate Operations

The following bivariate function replace *gps* with the result.

```
void    gps.intersection( General_polygon_set_2 gps1, General_polygon_set_2 gps2)
```

computes the intersection of *gps1* and *gps2*.

```
void    gps.join( General_polygon_set_2 gps1, General_polygon_set_2 gps2)
```

computes the union of *gps1* and *gps2*.

```
void    gps.difference( General_polygon_set_2 gps1, General_polygon_set_2 gps2)
```

computes the difference between *gps1* and *gps2*.

```
void    gps.symmetric_difference( General_polygon_set_2 gps1, General_polygon_set_2 gps2)
```

computes the symmetric difference between *gps1* and *gps2*.

Query Functions

<i>bool</i>	<i>gps.do_intersect(General_polygon_set_2 other)</i>	returns <i>true</i> if <i>gps</i> and <i>other</i> intersect in their interior, and <i>false</i> otherwise.
<i>bool</i>	<i>gps.do_intersect(Polygon_2 pgn)</i>	returns <i>true</i> if <i>gps</i> and <i>pgn</i> intersect in their interior, and <i>false</i> otherwise.
<i>bool</i>	<i>gps.do_intersect(Polygon_with_holes_2 pgn)</i>	returns <i>true</i> if <i>gps</i> and <i>pgn</i> intersect in their interior, and <i>false</i> otherwise.

```
template <class InputIterator>
void      gps.do_intersect( InputIterator begin, InputIterator end)
```

returns *true* if the interior of the point sets in a collection intersect, and *false* otherwise. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
void      gps.do_intersect( InputIterator1 pgn_begin,
                           InputIterator1 pgn_end,
                           InputIterator2 pgn_with_holes_begin,
                           InputIterator2 pgn_with_holes_end)
```

returns *true* if the interior of the point sets in a collection intersect, and *false* otherwise. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

<i>bool</i>	<i>gps.locate(Point_2 p, Polygon_with_holes_2 & pgn)</i>
-------------	---------------------------------------------------------------

obtains a polygon with holes that contains the query point *p*, if exists, through *pgn*, and returns *true*. Otherwise, returns *false*.

<i>Oriented_side</i>	<i>gps.oriented_side(Point_2 q)</i>
----------------------	--------------------------------------

returns either the constant *ON_ORIENTED_BOUNDARY*, *ON_POSITIVE_SIDE*, or *ON_NEGATIVE_SIDE*, iff *p* lies on the boundary, properly on the positive side, or properly on the negative side of *gps* respectively.

Oriented_side *gps.oriented_side(General_polygon_set_2 other)*

returns either the constant *ON_NEGATIVE_SIDE*, *ON_ORIENTED_BOUNDARY*, or *ON_POSITIVE_SIDE*, iff *other* and *gps* are completely disjoint, in contact, or intersect in their interior, respectively.

Oriented_side *gps.oriented_side(Polygon_2 pgn)*

returns either the constant *ON_NEGATIVE_SIDE*, *ON_ORIENTED_BOUNDARY*, or *ON_POSITIVE_SIDE*, iff *pgn* and *gps* are completely disjoint, in contact, or intersect in their interior, respectively.

Oriented_side *gps.oriented_side(Polygon_with_holes_2 pgn)*

returns either the constant *ON_NEGATIVE_SIDE*, *ON_ORIENTED_BOUNDARY*, or *ON_POSITIVE_SIDE*, iff *pgn* and *gps* are completely disjoint, in contact, or intersect in their interior, respectively.

Miscellaneous

bool *gps.is_valid()*

returns *true* if *gps* represents a valid point set.

GeneralPolygon_2

Types

<i>GeneralPolygon_2:: X_monotone_curve_2</i>	represents a planar (weakly) <i>x</i> -monotone curve. The type of the geometric mapping of the polygonal edges.
<i>GeneralPolygon_2:: Curve_iterator</i>	an iterator over the geometric mapping of the polygon edges. Its value type is <i>X_monotone_curve_2</i> .
<i>GeneralPolygon_2:: Curve_const_iterator</i>	a const iterator over the geometric mapping of the polygon edges. Its value type is <i>X_monotone_curve_2</i> .

Definition

A model of this concept represents a simple general-polygon. The geometric mapping of the edges of the polygon must be *x*-monotone curves. The concept requires the ability to access these curves. The general polygon represented must be simple. That is, the only points of the plane belonging to two curves are the geometric mapping of the polygon vertices. In addition, the vertices of the represented polygon must be ordered consistently, and the curved must be directed accordingly. Only counterclockwise orientated polygons are valid operands of Boolean set-operations. General polygon that represent holes must be clockwise orientated.

Creation

<i>GeneralPolygon_2 polygon;</i>	default constructor.
<i>GeneralPolygon_2 polygon(other);</i>	copy constructor.
<i>GeneralPolygon_2 polygon = other</i>	assignment operator.
<i>template <class InputIterator></i> <i>GeneralPolygon_2 polygon(InputIterator begin, InputIterator end);</i>	constructs a general polygon from a given range of curves.

Access Functions

<i>Curve_iterator</i>	<i>polygon.curves_begin()</i>	returns the begin iterator of the curves.
<i>Curve_iterator</i>	<i>polygon.curves_end()</i>	returns the past-the-end iterator of the curves.
<i>Curve_const_iterator</i>	<i>polygon.curves_begin()</i>	returns the begin const iterator of the curves.
<i>Curve_const_iterator</i>	<i>polygon.curves_end()</i>	returns the past-the-end const iterator of the curves.

Modifiers

template <class Iterator>

void

polygon.init(Iterator begin, Iterator end)

initializes the polygon with the polygonal chain given by the range. The value type of *Iterator* must be *X_monotone_curve_2*.

Precondition: The curves in the range must define a simple polygon.

Has Models

CGAL::General_polygon_2<ArrTraits>

GeneralPolygonWithHoles_2

Types

<i>GeneralPolygonWithHoles_2::General_polygon_2</i>	the general-polygon type used to represent the outer boundary and each hole.
<i>GeneralPolygonWithHoles_2::Hole_const_iterator</i>	a bidirectional iterator over the polygonal holes. Its value type is <i>General_polygon_2</i> .

Definition

A model of this concept represents a general polygon with holes. The concept requires the ability to access the general polygon that represents the outer boundary and the general polygons that represent the holes.

Creation

<i>GeneralPolygonWithHoles_2 polygon;</i>	default constructor.
<i>GeneralPolygonWithHoles_2 polygon(other);</i>	copy constructor.
<i>GeneralPolygonWithHoles_2 polygon = other</i>	assignment operator.

template <class InputIterator>

GeneralPolygonWithHoles_2 polygon(General_polygon_2 & outer, InputIterator begin, InputIterator end);

constructs a general polygon with holes using a given general polygon *outer* as the outer boundary and a given range of holes. If *outer* is an empty general polygon, then an unbounded polygon with holes will be created. The holes must be contained inside the outer boundary, and the polygons representing the holes must be strictly simple and pairwise disjoint, except perhaps at the vertices.

Predicates

<i>bool</i>	<i>polygon.is_unbounded()</i>	returns <i>true</i> if the outer boundary is empty, and <i>false</i> otherwise.
-------------	-------------------------------	---------------------------------------------------------------------------------

Access Functions

<i>General_polygon_2</i>	<i>polygon.outer_boundary()</i>	returns the general polygon that represents the outer boundary.
<i>Hole_const_iterator</i>	<i>polygon.holes_begin()</i>	returns the begin iterator of the holes.
<i>Hole_const_iterator</i>	<i>polygon.holes_end()</i>	returns the past-the-end iterator of the holes.

ArrangementDirectionalXMonotoneTraits_2

Definition

This concept refines the basic arrangement x -monotone traits concept. A model of this concept is able to handle *directed* x -monotone curves that intersect in their interior. Namely, an instance of the *X_monotone_curve_2* type defined by a model of the concept *ArrangementXMonotoneTraits_2* is only required to have a *left* (lexicographically smaller) endpoint and a *right* endpoint. If the traits class is also a model of *ArrangementDirectionalXMonotoneTraits_2*, the x -monotone curve is also required to have a direction, namely one of these two endpoint is viewed as its *source* and the other as its *target*.

Refines

ArrangementXMonotoneTraits_2

Functor Types

ArrangementDirectionalXMonotoneTraits_2:: Compare_endpoints_xy_2

provides the operator :

Comparison_result operator() (X_monotone_curve_2 c)

which accepts an input curve c and compare its source and target point. It returns *SMALLER* if the curve is directed from left to right (lexicographically — i.e., in case of a vertical line segment, this means it is directed upward), and *LARGER* if it is directed from right to left.

ArrangementDirectionalXMonotoneTraits_2:: Construct_opposite_2

provides the operator :

X_monotone_curve_2 operator() (X_monotone_curve_2 c)

which accepts an x -monotone curve c and returns its oppsite curve, namely a curve whose graph is the same as c 's, and whose source and target are swapped with respect to c 's source and target.

In addition, the two following functors, required by the concept *ArrangementXMonotoneTraits_2* should operate as follows:

ArrangementDirectionalXMonotoneTraits_2:: Intersect_2

provides the operator (templated by the *OutputIterator* type) :

OutputIterator operator() (X_monotone_curve_2 c1, X_monotone_curve_2 c2, OutputIterator oi)

which computes the intersections of $c1$ and $c2$ and inserts them *in an ascending lexicographic xy -order* into the output iterator. The value-type of *OutputIterator* is *CGAL::Object*, where each *Object* either wraps a *pair<Point_2,Multiplicity>* instance, which represents an intersection point with its multiplicity (in case the multiplicity is undefined or not known, it should be set to 0) or an *X_monotone_curve_2* instance, representing an overlapping subcurve of $c1$ and $c2$. In the latter case, if $c1$ and $c2$ have the same direction, then the overlapping subcurves should also be directed the same way; otherwise, they can be associated with an arbitrary direction. The operator returns a past-the-end iterator for the output sequence.

ArrangementDirectionalXMonotoneTraits_2:: Split_2

provides the operator :

```
void operator() (X_monotone_curve_2 c, Point_2 p, X_monotone_curve_2& c1, X_monotone_curve_2& c2)
```

which accepts an input curve *c* and a split point *p* in its interior. It splits *c* at the split point into two subcurves *c1* and *c2*, such that *p* is *c1*'s *right* endpoint and *c2*'s *left* endpoint. The direction of *c* should be preserved: in case *c* is directed from left to right then *p* becomes *c1*'s target and *c2*'s source; otherwise, *p* becomes *c2*'s target and *c1*'s source.

GeneralPolygonSetTraits_2

Definition

This concept defines the minimal set of geometric predicates needed to perform the Boolean-set operations. It refines the directional x -monotone arrangement-traits concept. In addition to the *Point_2* and *X_monotone_curve_2* types defined in the generalized concept, it defines a type that represents a general polygon and another one that represents general polygon with holes. It also requires operations that operate on these types.

Refines

ArrangementDirectionalXMonotoneTraits_2

Types

<i>GeneralPolygonSetTraits_2:: Polygon_2</i>	represents a general polygon.
<i>GeneralPolygonSetTraits_2:: Polygon_with_holes_2</i>	represents a general polygon with holes.
<i>GeneralPolygonSetTraits_2:: Curve_const_iterator</i>	A const iterator of curves. Its value type is const <i>X_monotone_curve_2</i> .

Functor Types

<i>GeneralPolygonSetTraits_2:: Construct_polygon_2</i>	a functor that constructs a general polygon from a range of x -monotone curves. It uses the operator <i>void operator() (InputIterator begin, Input iterator end, Polygon_2 & pgn)</i> , parameterized by the <i>InputIterator</i> type.
<i>GeneralPolygonSetTraits_2:: Construct_curves_2</i>	a functor that returns a pair that consists of the begin and past-the-end iterators of the x monotone curves of the boundary of a given general polygon. It uses the operator <i>std::pair<Curve_const_iterator, Curve_const_iterator> operator() (const Polygon_2 & pgn)</i> .

GeneralPolygonSetTraits_2::Is_valid_2

provides the operators :

bool operator() (Polygon_2 & pgn)

which returns *true* if the *pgn* is valid, and *false* otherwise;

and :

bool operator() (Polygon_with_holes_2 & pgn_with_holes)

which returns *true* if *pgn_with_holes* is valid, and *false* otherwise. A polygon of type *Polygon_2* is valid, if it is strictly simple and oriented counterclockwise. A polygon of type *Polygon_with_holes_2* is valid, if its outer boundary is simple and oriented counterclockwise, and each one of its holes is a strictly simple polygon that oriented clockwise, contained inside its outer boundary, and they are all together pairwise disjoint, except perhaps at the vertices.

This functionality is used to verify precondition of some of the operations.

Creation

GeneralPolygonSetTraits_2 traits;

default constructor.

GeneralPolygonSetTraits_2 traits(other);

copy constructor

GeneralPolygonSetTraits_2

traits = other

assignment operator.

Accessing Functor Objects

Construct_polygon_2 traits.construct_polygon_2_object()

returns a functor that constructs a polygon.

Construct_curves_2 traits.construct_curves_2_object()

returns a functor that obtains the curves of a polygon.

Is_valid_2 traits.is_valid_2_object()

returns a functor that checks the validity of a polygon.

CGAL::General_polygon_2<ArrTraits>

Definition

The class *General_polygon_2<ArrTraits>* models the concept *GeneralPolygon_2*. It represents a simple general-polygon. It is parameterized with the type *ArrTraits* that models the concept *ArrangementDirectionalXMonotoneTraits*. The latter is a refinement of the concept *ArrangementXMonotoneTraits_2*. In addition to the requirements of the concept *ArrangementXMonotoneTraits_2*, a model of the concept *ArrangementDirectionalXMonotoneTraits* must support the following functions:

- Given an *x*-monotone curve, construct its opposite curve.
- Given an *x*-monotone curve, compare its two endpoints lexicographically.

This class supports a few convenient operations in addition to the requirements that the concept *GeneralPolygon_2* lists.

```
#include <CGAL/General_polygon_2.h>
```

Types

General_polygon_2<ArrTraits>::Size number of edges size type.

Creation

Operations

Size *polygon.size()* returns the number of edges of *polygon*.

Modifiers

void *polygon.clear()* clears *polygon*.

void *polygon.reverse_orientation()* reverses the orientation of the polygon.
Precondition: is_simple().

Predicates

bool *polygon.is_empty()* returns *true* if *polygon* is empty, and *false* otherwise.

Orientation *polygon.orientation()* returns the orientation of *polygon*.
Precondition: is_simple().

                           Polygon_with_holes_2<Kernel, Container> p2,
                           OutputIterator oi)
```

```
template <class Kernel, class Container, class OutputIterator>
OutputIterator intersection( Polygon_with_holes_2<Kernel, Container> p1,
                           Polygon_2<Kernel, Container> p2,
                           OutputIterator oi)
```

```
template <class Kernel, class Container, class OutputIterator>
OutputIterator intersection( Polygon_with_holes_2<Kernel, Container> p1,
                           Polygon_with_holes_2<Kernel, Container> p2,
                           OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator intersection( General_polygon_2<Traits> p1,
                           General_polygon_2<Traits> p2,
                           OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator intersection( General_polygon_with_holes_2<General_polygon_2<Traits> > p1,
                           General_polygon_2<Traits> p2,
                           OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    intersection( General_polygon_2<Traits> p1,
                               General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                               OutputIterator oi)
```

```
template <class Polygon, class OutputIterator>
OutputIterator    intersection( General_polygon_with_holes_2<Polygon> p1,
                               General_polygon_with_holes_2<Polygon> p2,
                               OutputIterator oi)
```

```
template <class InputIterator, class OutputIterator>
OutputIterator    intersection( InputIterator begin, InputIterator end, OutputIterator oi)
```

Computes the intersection of the general polygons (or general polygons with holes) in the given range. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

```
template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator    intersection( InputIterator1 pgn_begin1,
                               InputIterator1 pgn_end1,
                               InputIterator2 pgn_begin2,
                               InputIterator2 pgn_end2,
                               OutputIterator oi)
```

Computes the intersection of the general polygons and general polygons with holes in the given two ranges. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

CGAL::join

Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
bool join( Type1 p1, Type2 p2, General_polygon_with_holes_2 & p)
```

Each one of these functions computes the union of two given polygons *p1* and *p2*. If the two given polygons overlap, it returns *true*, and places the resulting polygon in *p*. Otherwise, it returns *false*.

```

```
template <class Traits>
bool join( General_polygon_2<Traits> p1,
           General_polygon_2<Traits> p2,
           General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

```
template <class Traits>
bool join( General_polygon_2<Traits> p1,
           General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
           General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

```
template <class Traits>
bool      join( General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                General_polygon_2<Traits> p1,
                General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

```
template <class Polygon>
bool      join( General_polygon_with_holes_2<Polygon> p1,
                General_polygon_with_holes_2<Polygon> p2,
                Traits::Polygon_with_holes_2 & p)
```

```
template <class InputIterator, class OutputIterator>
OutputIterator  join( InputIterator begin, InputIterator end, OutputIterator oi)
```

Computes the union of the general polygons (or general polygons with holes) in the given range. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

```
template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator  join( InputIterator1 pgn_begin1,
                    InputIterator1 pgn_end1,
                    InputIterator2 pgn_begin2,
                    InputIterator2 pgn_end2,
                    OutputIterator oi)
```

Computes the union of the general polygons and general polygons with holes in the given two ranges. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

CGAL::symmetric_difference

Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
OutputIterator    intersection( Type1 p1, Type2 p2, OutputIterator oi)
```

Each one of these functions computes the symmetric difference between two given polygons *p1* and *p2*, and inserts the resulting polygons with holes into an output container through the output iterator *oi*. The value type of the *OutputIterator* is either *Polygon_with_holes_2* or *General_polygon_with_holes_2*.

                                       OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_2<Traits> p1,
                                       General_polygon_2<Traits> p2,
                                       OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_with_holes_2<General_polygon_2<Traits> > p1,
                                       General_polygon_2<Traits> p2,
                                       OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_2<Traits> p1,
                                     General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                                     OutputIterator oi)
```

```
template <class Polygon, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_with_holes_2<Polygon> p1,
                                     General_polygon_with_holes_2<Polygon> p2,
                                     OutputIterator oi)
```

```
template <class InputIterator, class OutputIterator>
OutputIterator    symmetric_difference( InputIterator begin, InputIterator end, OutputIterator oi)
```

Computes the symmetric difference of the general polygons (or general polygons with holes) in the given range. A point is contained in the symmetric difference, if and only if it is contained in odd number of input polygons. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

```
template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator    symmetric_difference( InputIterator1 pgn_begin1,
                                     InputIterator1 pgn_end1,
                                     InputIterator2 pgn_begin2,
                                     InputIterator2 pgn_end2,
                                     OutputIterator oi)
```

Computes the union of the general polygons and general polygons with holes in the given two ranges. A point is contained in the symmetric difference, if and only if it is contained in odd number of input polygons. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

CGAL::operator<<

Definition

This operator exports a polygon with holes, a general polygon, or a general polygon with holes P to the output stream *out*. The output is in ASCII format.

An ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, *set_ascii_mode* and *set_binary_mode* respectively. The modifier *set_pretty_mode* can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

```
#include <CGAL/Polygon_with_holes_2.h>          template <class Kernel, class Container>
ostream& out << CGAL::Polygon_with_holes_2<Kernel, Container> P
```

The number of points of the outer boundary is exported followed by the points themselves in counterclockwise order. Then, the number of holes is exported, and for each hole, the number of points on its outer boundary is exported followed by the points themselves in clockwise order.

```
#include <CGAL/General_polygon_2.h>             template <class ArrTraits>
ostream& out << CGAL::General_polygon_2<ArrTraits> P
```

The number of curves of the outer boundary is exported followed by the curves themselves in counterclockwise order.

```
#include <CGAL/General_polygon_with_holes_2.h>   template <class Polygon>
ostream& out << CGAL::General_polygon_with_holes_2<Polygon> P
```

The number of curves of the outer boundary is exported followed by the curves themselves in counterclockwise order. Then, the number of holes is exported, and for each hole, the number of curves on its outer boundary is exported followed by the curves themselves in clockwise order.

CGAL::operator>>

Definition

This operator imports a polygon with holes, a general polygon, or a general polygon with holes from the input stream *in*.

An ASCII and a binary format exist. The stream detects the format automatically and can read both.

```
#include <CGAL/Polygon_with_holes_2.h>          template <class Kernel, Class Container>
istream&                                         istream& in >> CGAL::Polygon_with_holes_2<Kernel, Container>& P
```

The format consists of the number of points of the outer boundary followed by the points themselves in counter-clockwise order, followed by the number of holes, and for each hole, the number of points of the outer boundary is followed by the points themselves in clockwise order.

```
#include <CGAL/General_polygon_2.h>             template <class ArrTraits>
istream&                                         istream& in >> CGAL::General_polygon_2<ArrTraits>& P
```

The format consists of the number of curves of the outer boundary followed by the curves themselves in counterclockwise order.

```
#include <CGAL/General_polygon_with_holes_2.h>  template <class Polygon>
istream&                                         istream& in >> CGAL::General_polygon_with_holes_2<Polygon>& P
```

The format consists of the number of curves of the outer boundary followed by the curves themselves in counter-clockwise order, followed by the number of holes, and for each hole, the number of curves on its outer boundary is followed by the curves themselves in clockwise order.

Chapter 13

2D Boolean Operations on Nef Polygons

Michael Seel

Contents

13.1 Introduction	953
13.2 Construction and Composition	954
13.3 Exploration	955
13.4 Traits Classes	956
13.5 Implementation	956

13.1 Introduction

When working with polygonal and polyhedral sets, the mathematical model determines the kind of point set that can be represented. Nef polyhedra are the most general rectilinear polyhedral model.

Topological simpler models that are contained in the domain of Nef polyhedra are:

- *convex polytopes* normally defined as the convex hull of a nonempty finite set of points. Convex polytopes are compact closed and manifold sets.
- *elementary polyhedra* normally defined as the union of a finite number of convex polytopes.
- *polyhedral sets* normally defined as the intersection of a finite number of closed halfspaces. Such sets are closed and convex but need not to be compact.
- *linear polyhedra* normally defined as the set of all points belonging to the simplices of a *simplicial complex*.

A planar *Nef polyhedron* is any set that can be obtained from a finite set of open halfspaces by set complement and set intersection operations. Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Apart from the set complement operation there are more topological unary set operations that are closed in the domain of Nef polyhedra. Given a Nef polyhedron one can determine its interior, its boundary, and its closure, and also composed operations like regularization (defined to be the closure of the interior or a point set).

Figure 13.1: Two Nef polyhedra in the plane. A closed halfspace on the left and a complex polyhedron on the right. Note that the points on the squared boundary are at infinity.

13.2 Construction and Composition

Following the above definition, the data type *Nef_polyhedron_2<T>* allows construction of elementary Nef polyhedra and the binary and unary composition by the mentioned set operations.

In the following examples skip the typedefs at the beginning at first and take the types *Point* and *Line* to be models of the standard two-dimensional CGAL kernel (*CGAL::Point_2<K>* and *CGAL::Line_2<K>*). Their user interface is thus defined in the corresponding reference pages.

```
// file : examples/Nef_2/construction.C

#include <CGAL/Gmpz.h>
#include <CGAL/Filtered_extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Filtered_extended_homogeneous<RT> Extended_kernel;
typedef CGAL::Nef_polyhedron_2<Extended_kernel> Nef_polyhedron;
typedef Nef_polyhedron::Point Point;
typedef Nef_polyhedron::Line Line;

int main() {

    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    Line l(2,4,2); // l : 2x + 4y + 2 = 0
    Nef_polyhedron N2(l,Nef_polyhedron::INCLUDED);
    Nef_polyhedron N3 = N2.complement();
    CGAL_assertion(N1 == N2.join(N3));

    Point p1(0,0), p2(10,10), p3(-20,15);
    Point triangle[3] = { p1, p2, p3 };
    Nef_polyhedron N4(triangle, triangle+3);
    Nef_polyhedron N5 = N2.intersection(N4);
    CGAL_assertion(N5 <= N2 && N5 <= N4);
```

```

    return 0;
}

```

Planar halfspaces (as used in the definition) are modelled by oriented lines. In the previous example $N1$ is the Nef polyhedron representing the full plane, $N2$ is the closed halfspace left of the oriented line with equation $2x + 4y + 2 = 0$ including the line, $N3$ is the complement of $N2$ and therefore it must hold that $N2 \cup N3 = N1$.

Additionally one can construct Nef polyhedra from iterator ranges that hold simple polygonal chains. In the example $N4$ is the triangle spanned by the vertices $(0,0)$, $(10,10)$, $(-20,15)$. Note that the construction from a simple polygonal chain has several cases and preconditions that are described in the reference manual page of *Nef_polyhedron_2<T>*. The *operator<=* in the last assertion is a subset-or-equal comparison of two polyhedra.

Nef polyhedra have input and output operators that allows one to output them via streams and read them from streams. Graphical output is currently possible to a *CGAL::Window_stream*. The output operation is defined in *CGAL/IO/Nef_polyhedron_2_Window_stream.h*. For an elaborate example see the demo programs in the directory *demo/Nef_2*.

13.3 Exploration

By recursively composing binary and unary operations one can end with a very complex rectilinear structure. To explore that structure there is a data type *Nef_polyhedron_2<T>::Explorer* that allows read-only exploration of the rectilinear structure. To understand its usability we need more knowledge about the representation of Nef polyhedra.

The rectilinear structure underlying a Nef polyhedron is stored in a selective plane map. Plane map here means a straightline embedded bidirected graph with face objects such that each point in the plane can be uniquely assigned to an object (vertex, edge, face) of the planar subdivision defined by the graph. Selective means that each object (vertex, edge, face) has a Boolean value associated with it to indicate set inclusion or exclusion.

The plane map is defined by the interface data type *Nef_polyhedron_2<T>::Topological_explorer*. Embedding the vertices by standard affine points does not suffice to model the unboundedness of halfspaces and ray-like structures. Therefore the planar subdivision is bounded symbolically by an axis-parallel square box of infimaximal size centered at the origin of our coordinate system. All structures extending to infinity are pruned by the box. Lines and rays have symbolic endpoints on the box. Faces are circularly closed. Infimaximal here means that its geometric extend is always large enough (but finite for our intuition). Assume you approach the box with an affine point, then this point is always inside the box. The same holds for straight lines; they always intersect the box. There are more accurate notions of “large enough”, but the previous propositions are enough at this point. Due to the fact that the infimaximal box is included in the plane map, the vertices and edges are partitioned with respect to this box.

Vertices inside the box are called standard vertices and they are embedded by affine points of type *Explorer::Point*. Vertices on the box are called non-standard vertices and they get their embedding where a ray intersects the box (their embedding is defined by an object of type *Explorer::Ray*). By their straightline embedding, edges represent either segments, rays, lines, or box segments depending on the character of their source and target vertices.

During exploration, box objects can be tracked down by the interface of *Nef_polyhedron_2<T>::Explorer* that is derived from *Nef_polyhedron_2<T>::Topological_explorer* and adds just the box exploration functionality to the interface of the latter. In the following code fragment we iterate over all vertices of a Nef polyhedron and check whether their embedding is an affine point or a point on the infimaximal frame.

```

typedef Nef_polyhedron::Explorer Explorer;
Explorer E = N4.explorer();
Explorer::Vertex_const_iterator v;
for (v = E.vertices_begin(); v != E.vertices_end(); ++v)
    if ( E.is_standard(v) )
        Explorer::Point p = E.point(v) // affine embedding of v
    else /* non-standard */
        Explorer::Ray r = E.ray(v) // extended embedding of v

```

Note that box edges only serve as boundary edges (combinatorically) to close the faces that extend to infinity (geometrically). Their status can be queried by the following operation:

```

typedef Nef_polyhedron::Explorer Explorer;
Explorer E = N4.explorer();
Explorer::Halfedge_const_iterator e;
for (e = E.halfedges_begin(); e != E.halfedges_end(); ++e)
    if ( E.is_frame_edge(e) ) // e is part of square box.

```

13.4 Traits Classes

Now finally we clarify what the template parameter of class *Nef_polyhedron_2*<*T*> actually models. *T* carries the implementation of a so-called extended geometric kernel.

Currently there are three kernel models: *CGAL::Extended_cartesian*<*FT*>, *CGAL::Extended_homogeneous*<*RT*>, and *CGAL::Filtered_extended_homogeneous*<*RT*>. The latter is the most optimized one. The former two are simpler versions corresponding to the simple planar affine kernels. Actually, it holds that (type equality in pseudo-code notation):

```

CGAL::Nef_polyhedron_2< CGAL::Extended_cartesian<FT> >::Point
== CGAL::Cartesian<FT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Extended_homogeneous<RT> >::Point
== CGAL::Homogeneous<RT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Filtered_extended_homogeneous<RT> >::Point
== CGAL::Homogeneous<RT>::Point_2

```

Similar equations hold for the types *Line* and *Direction* in the local scope of *Nef_polyhedron_2*<...>.

— advanced —

For its notions and requirements see the description of the concept *ExtendedKernelTraits_2* in the reference manual.

— advanced —

13.5 Implementation

The underlying set operations are realized by an efficient and complete algorithm for the overlay of two plane maps. The algorithm is efficient in the sense that its running time is bounded by the size of the inputs plus the

size of the output times a logarithmic factor. The algorithm is complete in the sense that it can handle all inputs and requires no general position assumption.

2D Boolean Operations on Nef Polygons

Reference Manual

Michael Seel

Planar Nef Polyhedra are whatever can be constructed with a finite number of Boolean operations on halfspaces. See the user manual pages for a detailed introduction.

CGAL::Nef_polyhedron_2<T>

Definition

An instance of data type *Nef_polyhedron_2<T>* is a subset of the plane that is the result of forming complements and intersections starting from a finite set *H* of halfspaces. *Nef_polyhedron_2* is closed under all binary set operations *intersection*, *union*, *difference*, *complement* and under the topological operations *boundary*, *closure*, and *interior*.

The template parameter *T* is specified via an extended kernel concept. *T* must be a model of the concept *ExtendedKernelTraits_2*.

```
#include <CGAL/Nef_polyhedron_2.h>
```

Types

Nef_polyhedron_2<T>::Line the oriented lines modeling halfplanes

Nef_polyhedron_2<T>::Point the affine points of the plane.

Nef_polyhedron_2<T>::Direction directions in our plane.

enum Boundary { *EXCLUDED*, *INCLUDED* }; construction selection.

enum Content { *EMPTY*, *COMPLETE* }; construction selection

Creation

```
Nef_polyhedron_2<T> N( Content plane = EMPTY );
```

creates an instance *N* of type *Nef_polyhedron_2<T>* and initializes it to the empty set if *plane* == *EMPTY* and to the whole plane if *plane* == *COMPLETE*.

```
Nef_polyhedron_2<T> N( Line l, Boundary line = INCLUDED );
```

creates a Nef polyhedron *N* containing the halfplane left of *l* including *l* if *line*==*INCLUDED*, excluding *l* if *line*==*EXCLUDED*.

```
template <class Forward_iterator>
```

```
Nef_polyhedron_2<T> N( Forward_iterator it, Forward_iterator end, Boundary b = INCLUDED );
```

creates a Nef polyhedron *N* from the simple polygon *P* spanned by the list of points in the iterator range *[it,end)* and including its boundary if *b* = *INCLUDED* excluding the boundary otherwise. *Forward_iterator* has to be an iterator with value type *Point*. This construction expects that *P* is simple. The degenerate cases where *P* contains no point, one point or spans just one segment (two points) are correctly handled. In all degenerate cases there's only one unbounded face adjacent to the degenerate polygon. If *b* == *INCLUDED* then *N* is just the boundary. If *b* == *EXCLUDED* then *N* is the whole plane without the boundary.

Operations

<i>void</i>	<i>N.clear(Content plane = EMPTY)</i>	makes <i>N</i> the empty set if <i>plane</i> == <i>EMPTY</i> and the full plane if <i>plane</i> == <i>COMPLETE</i> .
<i>bool</i>	<i>N.is_empty()</i>	returns true if <i>N</i> is empty, false otherwise.
<i>bool</i>	<i>N.is_plane()</i>	returns true if <i>N</i> is the whole plane, false otherwise.

Constructive Operations

<i>Nef_polyhedron_2<T></i>	<i>N.complement()</i>	returns the complement of <i>N</i> in the plane.
<i>Nef_polyhedron_2<T></i>	<i>N.interior()</i>	returns the interior of <i>N</i> .
<i>Nef_polyhedron_2<T></i>	<i>N.closure()</i>	returns the closure of <i>N</i> .
<i>Nef_polyhedron_2<T></i>	<i>N.boundary()</i>	returns the boundary of <i>N</i> .
<i>Nef_polyhedron_2<T></i>	<i>N.regularization()</i>	returns the regularized polyhedron (closure of interior).
<i>Nef_polyhedron_2<T></i>	<i>N.intersection(N1)</i>	returns $N \cap N1$.
<i>Nef_polyhedron_2<T></i>	<i>N.join(N1)</i>	returns $N \cup N1$. Note that “union” is a keyword of C++ and cannot be used for this operation.
<i>Nef_polyhedron_2<T></i>	<i>N.difference(N1)</i>	returns $N - N1$.
<i>Nef_polyhedron_2<T></i>	<i>N.symmetric_difference(N1)</i>	returns the symmetric difference $N - T \cup T - N$.

Additionally there are operators $*, +, -, \wedge, !$ which implement the binary operations *intersection*, *join*, *difference*, *symmetric difference*, and the unary operation *complement*, respectively. There are also the corresponding modification operations $*=, +=, -=, \wedge=$.

There are also comparison operations like $<, <=, >, >=, ==, !=$ which implement the relations subset, subset or equal, superset, superset or equal, equality, inequality, respectively.

Exploration - Point location - Ray shooting

As Nef polyhedra are the result of forming complements and intersections starting from a set *H* of halfspaces that are defined by oriented lines in the plane, they can be represented by an attributed plane map $M = (V, E, F)$. For topological queries within *M* the following types and operations allow exploration access to this structure.

Types

Nef_polyhedron_2<T>:: Explorer

a decorator to examine the underlying plane map. See the manual page of *Explorer*.

Nef_polyhedron_2<T>:: Object_handle

a generic handle to an object of the underlying plane map. The kind of object (*vertex*, *halfedge*, *face*) can be determined and the object can be assigned to a corresponding handle by the three functions:

bool assign(Vertex_const_handle& h, Object_handle)

bool assign(Halfedge_const_handle& h, Object_handle)

bool assign(Face_const_handle& h, Object_handle)

where each function returns *true* iff the assignment to *h* was done.

enum Location_mode { DEFAULT, NAIVE, LMWT};

selection flag¹ for the point location mode.

Operations

bool N.contains(Object_handle h)

returns true iff the object *h* is contained in the set represented by *N*.

bool N.contained_in_boundary(Object_handle h)

returns true iff the object *h* is contained in the 1-skeleton of *N*.

Object_handle N.locate(Point p, Location_mode m = DEFAULT)

returns a generic handle *h* to an object (face, halfedge, vertex) of the underlying plane map that contains the point *p* in its relative interior. The point *p* is contained in the set represented by *N* if *N.contains(h)* is true. The location mode flag *m* allows one to choose between different point location strategies.

Object_handle N.ray_shoot(Point p, Direction d, Location_mode m = DEFAULT)

returns a handle *h* with *N.contains(h)*, that can be converted to a *Vertex_*/*Halfedge_*/*Face_const_handle* as described above. The object returned is intersected by the ray starting in *p* with direction *d* and has minimal distance to *p*. The operation returns the null handle *NULL* if the ray shoot along *d* does not hit any object *h* of *N* with *N.contains(h)*. The location mode flag *m* allows one to choose between different point location strategies.

Object_handle *N.ray_shoot_to_boundary(Point p, Direction d, Location_mode m = DEFAULT)*

returns a handle *h*, that can be converted to a *Vertex/Halfedge_const_handle* as described above. The object returned is part of the 1-skeleton of *N*, intersected by the ray starting in *p* with direction *d* and has minimal distance to *p*. The operation returns the null handle *NULL* if the ray shoot along *d* does not hit any 1-skeleton object *h* of *N*. The location mode flag *m* allows one to choose between different point location strategies.

Explorer *N.explorer()*

returns a decorator object that allows read-only access of the underlying plane map. See the manual page *Explorer* for its usage.

Input and Output

A Nef polyhedron *N* can be visualized in a *Window_stream W*. The output operator is defined in the file *CGAL/IO/Nef_polyhedron_2_Window_stream.h*.

Implementation

Nef polyhedra are implemented on top of a halfedge data structure and use linear space in the number of vertices, edges and facets. Operations like *empty* take constant time. The operations *clear*, *complement*, *interior*, *closure*, *boundary*, *regularization*, input and output take linear time. All binary set operations and comparison operations take time $O(n \log n)$ where *n* is the size of the output plus the size of the input.

The point location and ray shooting operations are implemented in two flavors. The *NAIVE* operations run in linear query time without any preprocessing, the *DEFAULT* operations (equals *LMWT*) run in sub-linear query time, but preprocessing is triggered with the first operation. Preprocessing takes time $O(N^2)$, the sub-linear point location time is either logarithmic when LEDA's persistent dictionaries are present or if not then the point location time is worst-case linear, but experiments show often sublinear runtimes. Ray shooting equals point location plus a walk in the constrained triangulation overlayed on the plane map representation. The cost of the walk is proportional to the number of triangles passed in direction *d* until an obstacle is met. In a minimum weight triangulation of the obstacles (the plane map representing the polyhedron) the theory provides a $O(\sqrt{n})$ bound for the number of steps. Our locally minimum weight triangulation approximates the minimum weight triangulation only heuristically (the calculation of the minimum weight triangulation is conjectured to be NP hard). Thus we have no runtime guarantee but a strong experimental motivation for its approximation.

Example

Nef polyhedra are parameterized by a so-called extended geometric kernel. There are three kernels, one based on a homogeneous representation of extended points called *Extended_homogeneous<RT>* where *RT* is a ring type providing additionally a *gcd* operation, one based on a Cartesian representation of extended points called *Extended_cartesian<NT>* where *NT* is a field type, and finally *Filtered_extended_homogeneous<RT>* (an optimized version of the first). The following example uses the filtered homogeneous kernel to construct the intersection of two halfspaces.

```
// file : examples/Nef_2/simple_intersection.C

#include <CGAL/Gmpz.h>
```

```

#include <CGAL/Filtered_extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Filtered_extended_homogeneous<RT> Extended_kernel;
typedef CGAL::Nef_polyhedron_2<Extended_kernel> Nef_polyhedron;
typedef Nef_polyhedron::Line Line;

int main()
{
    Nef_polyhedron N1(Line(1,0,0));
    Nef_polyhedron N2(Line(0,1,0), Nef_polyhedron::EXCLUDED);
    Nef_polyhedron N3 = N1 * N2; // line (*)
    return 0;
}

```

After line (*) *N3* is the intersection of *N1* and *N2*. The member types of *Nef_polyhedron_2< Extended_homogeneous<NT> >* map to corresponding types of the standard CGAL geometry kernel (type equality in pseudo-code notation):

```

CGAL::Nef_polyhedron_2< CGAL::Extended_cartesian<FT> >::Point
    == CGAL::Cartesian<FT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Extended_homogeneous<RT> >::Point
    == CGAL::Homogeneous<RT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Filtered_extended_homogeneous<RT> >::Point
    == CGAL::Homogeneous<RT>::Point_2

```

The same holds for the types *Line* and *Direction* in the local scope of *Nef_polyhedron_2<...>*.

CGAL::Topological_explorer

Definition

An instance D of the data type *Topological_explorer* is a decorator for interfacing the topological structure of a plane map P (read-only).

A plane map P consists of a triple (V, E, F) of vertices, edges, and faces. We collectively call them objects. An edge e is a pair of vertices (v, w) with incidence operations $v = \text{source}(e)$, $w = \text{target}(e)$. The list of all edges with source v is called the adjacency list $A(v)$.

Edges are paired into twins. For each edge $e = (v, w)$ there's an edge $\text{twin}(e) = (w, v)$ and $\text{twin}(\text{twin}(e)) = e$ ².

An edge $e = (v, w)$ knows two adjacent edges $en = \text{next}(e)$ and $ep = \text{previous}(e)$ where $\text{source}(en) = w$, $\text{previous}(en) = e$ and $\text{target}(ep) = v$ and $\text{next}(ep) = e$. By this symmetric *previous-next* relationship all edges are partitioned into face cycles. Two edges e and e' are in the same face cycle if $e = \text{next}^*(e')$. All edges e in the same face cycle have the same incident face $f = \text{face}(e)$. The cyclic order on the adjacency list of a vertex $v = \text{source}(e)$ is given by $\text{cyclic_adj_succ}(e) = \text{twin}(\text{previous}(e))$ and $\text{cyclic_adj_pred}(e) = \text{next}(\text{twin}(e))$.

A vertex v is embedded via coordinates $\text{point}(v)$. By the embedding of its source and target an edge corresponds to a segment. P has the property that the embedding is always *order-preserving*. This means a ray fixed in $\text{point}(v)$ of a vertex v and swept around counterclockwise meets the embeddings of $\text{target}(e)$ ($e \in A(v)$) in the cyclic order defined by the list order of A .

The embedded face cycles partition the plane into maximal connected subsets of points. Each such set corresponds to a face. A face is bounded by its incident face cycles. For all the edges in the non-trivial face cycles it holds that the face is left of the edges. There can also be trivial face cycles in form of isolated vertices in the interior of a face. Each such vertex v knows its surrounding face $f = \text{face}(v)$.

Plane maps are attributed, for each object $u \in V \cup E \cup F$ we attribute an information $\text{mark}(u)$ of type *Mark*. *Mark* fits the concepts assignable, default-constructible, and equal-comparable.

Types

<i>Topological_explorer::Plane_map</i>	The underlying plane map type
<i>Topological_explorer::Point</i>	The point type of vertices.
<i>Topological_explorer::Mark</i>	All objects (vertices, edges, faces) are attributed by a <i>Mark</i> object.
<i>Topological_explorer::Size_type</i>	The size type.

Local types are handles, iterators and circulators of the following kind: *Vertex_const_handle*, *Vertex_const_iterator*, *Halfedge_const_handle*, *Halfedge_const_iterator*, *Face_const_handle*, *Face_const_iterator*. Additionally the following circulators are defined.

Topological_explorer::Halfedge_around_vertex_const_circulator

circulating the outgoing halfedges in $A(v)$.

²The existence of the edge pairs makes P a bidirected graph, the *twin* links make P a map.

Topological_explorer:: Halfedge_around_face_const_circulator

circulating the halfedges in the face cycle of a face f .

Topological_explorer:: Hole_const_iterator

iterating all holes of a face f . The type is convertible to *Halfedge_const_handle*.

Topological_explorer:: Isolated_vertex_const_iterator

iterating all isolated vertices of a face f . The type generalizes *Vertex_const_handle*.

Operations

Vertex_const_handle

D.source(Halfedge_const_handle e)

returns the source of e .

Vertex_const_handle

D.target(Halfedge_const_handle e)

returns the target of e .

Halfedge_const_handle

D.twin(Halfedge_const_handle e)

returns the twin of e .

bool

D.is_isolated(Vertex_const_handle v)

returns *true* iff $A(v) = \emptyset$.

Halfedge_const_handle

D.first_out_edge(Vertex_const_handle v)

returns one halfedge with source v . It's the starting point for the circular iteration over the halfedges with source v .

Precondition: !is_isolated(v).

Halfedge_const_handle

D.last_out_edge(Vertex_const_handle v)

returns the halfedge with source v that is the last in the circular iteration before encountering *first_out_edge(v)* again.

Precondition: !is_isolated(v).

Halfedge_const_handle

D.cyclic_adj_succ(Halfedge_const_handle e)

returns the edge after e in the cyclic ordered adjacency list of *source(e)*.

<i>Halfedge_const_handle</i>	<i>D.cyclic_adj_pred(Halfedge_const_handle e)</i>	returns the edge before <i>e</i> in the cyclic ordered adjacency list of <i>source(e)</i> .
<i>Halfedge_const_handle</i>	<i>D.next(Halfedge_const_handle e)</i>	returns the next edge in the face cycle containing <i>e</i> .
<i>Halfedge_const_handle</i>	<i>D.previous(Halfedge_const_handle e)</i>	returns the previous edge in the face cycle containing <i>e</i> .
<i>Face_const_handle</i>	<i>D.face(Halfedge_const_handle e)</i>	returns the face incident to <i>e</i> .
<i>Face_const_handle</i>	<i>D.face(Vertex_const_handle v)</i>	returns the face incident to <i>v</i> . <i>Precondition: is_isolated(v)</i> .
<i>Halfedge_const_handle</i>	<i>D.halfedge(Face_const_handle f)</i>	returns a halfedge in the bounding face cycle of <i>f</i> (<i>Halfedge_const_handle()</i>) if there is no bounding face cycle).

Iteration

<i>Vertex_const_iterator</i>	<i>D.vertices_begin()</i>	iterator over vertices of the map.
<i>Vertex_const_iterator</i>	<i>D.vertices_end()</i>	past-the-end iterator for vertices.
<i>Halfedge_const_iterator</i>	<i>D.halfedges_begin()</i>	iterator over halfedges of the map.
<i>Halfedge_const_iterator</i>	<i>D.halfedges_end()</i>	past-the-end iterator for halfedges.
<i>Face_const_iterator</i>	<i>D.faces_begin()</i>	iterator over faces of the map.
<i>Face_const_iterator</i>	<i>D.faces_end()</i>	past-the-end iterator for faces

Halfedge_around_vertex_const_circulator

D.out_edges(Vertex_const_handle v)

returns a circulator for the cyclic adjacency list of *v*.

Halfedge_around_face_const_circulator

D.face_cycle(Face_const_handle f)

returns a circulator for the outer face cycle of *f*.

Hole_const_iterator

D.holes_begin(Face_const_handle f)

returns an iterator for all holes in the interior of *f*. A *Hole_iterator* can be assigned to a *Halfedge_around_face_const_circulator*.

Hole_const_iterator

D.holes_end(Face_const_handle f)

returns the past-the-end iterator of *f*.

Isolated_vertex_const_iterator

D.isolated_vertices_begin(Face_const_handle f)

returns an iterator for all isolated vertices in the interior of *f*.

Isolated_vertex_const_iterator

D.isolated_vertices_end(Face_const_handle f)

returns the past the end iterator of *f*.

Associated Information

The type *Mark* is the general attribute of an object.

Point

D.point(Vertex_const_handle v)

returns the embedding of *v*.

Mark

D.mark(Vertex_const_handle v)

returns the mark of *v*.

<i>Mark</i>	<i>D.mark(Halfedge_const_handle e)</i>	returns the mark of <i>e</i> .
<i>Mark</i>	<i>D.mark(Face_const_handle f)</i>	returns the mark of <i>f</i> .
Statistics and Integrity		
<i>Size_type</i>	<i>D.number_of_vertices()</i>	returns the number of vertices.
<i>Size_type</i>	<i>D.number_of_halfedges()</i>	returns the number of halfedges.
<i>Size_type</i>	<i>D.number_of_edges()</i>	returns the number of halfedge pairs.
<i>Size_type</i>	<i>D.number_of_faces()</i>	returns the number of faces.
<i>Size_type</i>	<i>D.number_of_face_cycles()</i>	returns the number of face cycles.
<i>Size_type</i>	<i>D.number_of_connected_components()</i>	calculates the number of connected components of <i>P</i> .
<i>void</i>	<i>D.print_statistics(std::ostream& os = std::cout)</i>	print the statistics of <i>P</i> : the number of vertices, edges, and faces.
<i>void</i>	<i>D.check_integrity_and_topological_planarity(bool faces=true)</i>	checks the link structure and the genus of <i>P</i> .

CGAL::Explorer

Definition

An instance E of the data type *Explorer* is a decorator to explore the structure of the plane map underlying the Nef polyhedron. It inherits all topological adjacency exploration operations from *Topological_explorer*. *Explorer* additionally allows one to explore the geometric embedding.

The position of each vertex is given by a so-called extended point, which is either a standard affine point or the tip of a ray touching an infinimaximal square frame centered at the origin. A vertex v is called a *standard* vertex if its embedding is a *standard* point and *non-standard* if its embedding is a *non-standard* point. By the straightline embedding of their source and target vertices, edges correspond to either affine segments, rays or lines or are part of the bounding frame.

Figure 13.2: Extended geometry: standard vertices are marked by S, non-standard vertices are marked by N. **A:** The possible embeddings of edges: an affine segment $s1$, an affine ray $s2$, an affine line $s3$. **B:** A plane map embedded by extended geometry: note that the frame is arbitrarily large, the 6 vertices on the frame are at infinity, the two faces represent a geometrically unbounded area, however they are topologically closed by the frame edges. No standard point can be placed outside the frame.

Inherits From

Topological_explorer

Types

Explorer::Point the point type of finite vertices.

Explorer::Ray the ray type of vertices on the frame.

Iterators, handles, and circulators are inherited from *Topological_explorer*.

Creation

Explorer is copy constructable and assignable. An object can be obtained via the *Nef_polyhedron_2::explorer()* method of *Nef_polyhedron_2*.

Operations

bool *E.is_standard(Vertex_const_handle v)*

returns true iff *v*'s position is a standard point.

Point *E.point(Vertex_const_handle v)*

returns the standard point that is the embedding of *v*.

Precondition: E.is_standard(v).

Ray *E.ray(Vertex_const_handle v)*

returns the ray defining the non-standard point on the frame.

Precondition: !E.is_standard(v).

bool *E.is_frame_edge(Halfedge_const_handle e)*

returns true iff *e* is part of the infinimaximal frame.

ExtendedKernelTraits_2

Definition

ExtendedKernelTraits_2 is a kernel concept providing extended geometry³. Let K be an instance of the data type *ExtendedKernelTraits_2*. The central notion of extended geomtry are extended points. An extended point represents either a standard affine point of the Cartesian plane or a non-standard point representing the equivalence class of rays where two rays are equivalent if one is contained in the other.

Let R be an infinimaximal number⁴, F be the square box with corners $NW(-R, R)$, $NE(R, R)$, $SE(R, -R)$, and $SW(-R, -R)$. Let p be a non-standard point and let r be a ray defining it. If the frame F contains the source point of r then let $p(R)$ be the intersection of r with the frame F , if F does not contain the source of r then $p(R)$ is undefined. For a standard point let $p(R)$ be equal to p if p is contained in the frame F and let $p(R)$ be undefined otherwise. Clearly, for any standard or non-standard point p , $p(R)$ is defined for any sufficiently large R . Let f be any function on standard points, say with k arguments. We call f *extensible* if for any k points p_1, \dots, p_k the function value $f(p_1(R), \dots, p_k(R))$ is constant for all sufficiently large R . We define this value as $f(p_1, \dots, p_k)$. Predicates like lexicographic order of points, orientation, and incircle tests are extensible.

An extended segment is defined by two extended points such that it is either an affine segment, an affine ray, an affine line, or a segment that is part of the square box. Extended directions extend the affine notion of direction to extended objects.

This extended geometry concept serves two purposes. It offers functionality for changing between standard affine and extended geometry. At the same time it provides extensible geometric primitives on the extended geometric objects.

Types

Affine kernel types

<i>ExtendedKernelTraits_2::Standard_kernel</i>	the standard affine kernel.
<i>ExtendedKernelTraits_2::Standard_RT</i>	the standard ring type.
<i>ExtendedKernelTraits_2::Standard_point_2</i>	standard points.
<i>ExtendedKernelTraits_2::Standard_segment_2</i>	standard segments.
<i>ExtendedKernelTraits_2::Standard_line_2</i>	standard oriented lines.
<i>ExtendedKernelTraits_2::Standard_direction_2</i>	standard directions.
<i>ExtendedKernelTraits_2::Standard_ray_2</i>	standard rays.

³It is called extended geometry for simplicity, though it is not a real geometry in the classical sense.

⁴A finite but very large number.

ExtendedKernelTraits_2:: Standard_aff_transformation_2

standard affine transformations.

Extended kernel types

ExtendedKernelTraits_2:: RT

the ring type of our extended kernel.

ExtendedKernelTraits_2:: Point_2

extended points.

ExtendedKernelTraits_2:: Segment_2

extended segments.

ExtendedKernelTraits_2:: Direction_2

extended directions.

```
enum Point_type { SWCORNER,
                  LEFTFRAME,
                  NWCORNER,
                  BOTTOMFRAME,
                  STANDARD,
                  TOPFRAME,
                  SECORNER,
                  RIGHTFRAME,
                  NECORNER }
```

a type descriptor for extended points.

Operations

Interfacing the affine kernel types

Point_2 *K.construct_point(Standard_point_2 p)*

creates an extended point and initializes it to the standard point *p*.

Point_2 *K.construct_point(Standard_line_2 l)*

creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line *l*.

Point_2 *K.construct_point(Standard_point_2 p1, Standard_point_2 p2)*

creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line *l(p1,p2)*.

<i>Point_2</i>	<i>K.construct_point(Standard_point_2 p, Standard_direction_2 d)</i>	creates an extended point and initializes it to the equivalence class of all the rays underlying the ray starting in <i>p</i> in direction <i>d</i> .
<i>Point_2</i>	<i>K.construct_opposite_point(Standard_line_2 l)</i>	creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line opposite to <i>l</i> .
<i>Point_type</i>	<i>K.type(Point_2 p)</i>	determines the type of <i>p</i> and returns it.
<i>bool</i>	<i>K.is_standard(Point_2 p)</i>	returns <i>true</i> iff <i>p</i> is a standard point.
<i>Standard_point_2</i>	<i>K.standard_point(Point_2 p)</i>	returns the standard point represented by <i>p</i> . <i>Precondition: K.is_standard(p).</i>
<i>Standard_line_2</i>	<i>K.standard_line(Point_2 p)</i>	returns the oriented line representing the bundle of rays defining <i>p</i> . <i>Precondition: !K.is_standard(p).</i>
<i>Standard_ray_2</i>	<i>K.standard_ray(Point_2 p)</i>	a ray defining <i>p</i> . <i>Precondition: !K.is_standard(p).</i>
<i>Point_2</i>	<i>K.NE()</i>	returns the point on the northeast frame corner.
<i>Point_2</i>	<i>K.SE()</i>	returns the point on the southeast frame corner.
<i>Point_2</i>	<i>K.NW()</i>	returns the point on the northwest frame corner.
<i>Point_2</i>	<i>K.SW()</i>	returns the point on the southwest frame corner.

Geometric kernel calls

<i>Point_2</i>	<i>K.source(Segment_2 s)</i>	returns the source point of <i>s</i> .
----------------	-------------------------------	----------------------------------------

<i>Point_2</i>	<i>K.target(Segment_2 s)</i>	returns the target point of <i>s</i> .
<i>Segment_2</i>	<i>K.construct_segment(Point_2 p, Point_2 q)</i>	constructs a segment <i>pq</i> .
<i>int</i>	<i>K.orientation(Segment_2 s, Point_2 p)</i>	returns the orientation of <i>p</i> with respect to the line through <i>s</i> .
<i>int</i>	<i>K.orientation(Point_2 p1, Point_2 p2, Point_2 p3)</i>	returns the orientation of <i>p3</i> with respect to the line through <i>p1p2</i> .
<i>bool</i>	<i>K.left_turn(Point_2 p1, Point_2 p2, Point_2 p3)</i>	return true iff the <i>p3</i> is left of the line through <i>p1p2</i> .
<i>bool</i>	<i>K.is_degenerate(Segment_2 s)</i>	return true iff <i>s</i> is degenerate.
<i>int</i>	<i>K.compare_xy(Point_2 p1, Point_2 p2)</i>	returns the lexicographic order of <i>p1</i> and <i>p2</i> .
<i>int</i>	<i>K.compare_x(Point_2 p1, Point_2 p2)</i>	returns the order on the <i>x</i> -coordinates of <i>p1</i> and <i>p2</i> .
<i>int</i>	<i>K.compare_y(Point_2 p1, Point_2 p2)</i>	returns the order on the <i>y</i> -coordinates of <i>p1</i> and <i>p2</i> .
<i>Point_2</i>	<i>K.intersection(Segment_2 s1, Segment_2 s2)</i>	returns the point of intersection of the lines supported by <i>s1</i> and <i>s2</i> . <i>Precondition:</i> the intersection point exists.
<i>Direction_2</i>	<i>K.construct_direction(Point_2 p1, Point_2 p2)</i>	returns the direction of the vector <i>p2 - p1</i> .

<i>bool</i>	<i>K.strictly_ordered_ccw(Direction_2 d1, Direction_2 d2, Direction_2 d3)</i>	returns <i>true</i> iff <i>d2</i> is in the interior of the counterclockwise angular sector between <i>d1</i> and <i>d3</i> .
<i>bool</i>	<i>K.strictly_ordered_along_line(Point_2 p1, Point_2 p2, Point_2 p3)</i>	returns <i>true</i> iff <i>p2</i> is in the relative interior of the segment <i>p1p3</i> .
<i>bool</i>	<i>K.contains(Segment_2 s, Point_2 p)</i>	returns <i>true</i> iff <i>s</i> contains <i>p</i> .
<i>bool</i>	<i>K.first_pair_closer_than_second(Point_2 p1, Point_2 p2, Point_2 p3, Point_2 p4)</i>	returns <i>true</i> iff $\ p1 - p2\ < \ p3 - p4\ $.
<i>const char*</i>	<i>K.output_identifier()</i>	returns a unique identifier for kernel object Input/Output. Usually this should be the name of the model.

Has Models

<i>CGAL::Extended_cartesian<FT></i>	page 977
<i>CGAL::Extended_homogeneous<RT></i>	page 978
<i>CGAL::Filtered_extended_homogeneous<RT></i>	page 979

CGAL::Extended_cartesian<FT>

Definition

The class *Extended_cartesian*<FT> serves as a traits class for the class *CGAL::Nef_polyhedron_2*<T>. It uses a polynomial component representation based on a field number type *FT*.

```
#include <CGAL/Extended_cartesian.h>
```

Is Model for the Concepts

ExtendedKernelTraits_2 page [972](#)

Creation

Extended_cartesian<FT> traits; default constructor.

Requirements

To make a field number type *FT_model* work with this class, you must provide a traits class for this number type: *CGAL::Number_type_traits*<FT_model> (See the support library manual.)

Operations

Fits all operation requirements of the concept.

See Also

CGAL::Extended_homogeneous<RT> page [978](#)
CGAL::Filtered_extended_homogeneous<RT> page [979](#)

CGAL::Extended_homogeneous<RT>

Definition

The class *Extended_homogeneous<RT>* serves as a traits class for the class *CGAL::Nef_polyhedron_2<T>*. It uses a polynomial component representation based on a Euclidean ring number type *RT*.

`#include <CGAL/Extended_homogeneous.h>`

Is Model for the Concepts

ExtendedKernelTraits_2 page [972](#)

Creation

Extended_homogeneous<RT> traits; default constructor.

Requirements

To make an Euclidean ring number type *RT_model* work with this class the number type must support a gcd computation in namespace *CGAL::NTS*. CGAL provides a function template for this, which will be used by default when your number type is not one of the built-in number types, one of the number types distributed with CGAL or one of the LEDA number types.

Operations

Fits all operation requirements of the concept.

14.1 Introduction

Nef polyhedra are defined as a subset of the d -dimensional space obtained by a finite number of set complement and set intersection operations on halfspaces.

Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Also, Nef polyhedra are closed under topological unary set operations. Given a Nef polyhedron one can determine its interior, its boundary, and its closure.

Additionally, a d -dimensional Nef polyhedron has the property, that its boundary is a $(d-1)$ -dimensional Nef polyhedron. This property can be used as a way to represent 3-dimensional Nef polyhedra by means of planar Nef polyhedra. This is done by intersecting the neighborhood of a vertex in a 3D Nef polyhedron with an ε -sphere. The result is a planar Nef polyhedron embedded on the sphere.

The intersection of a halfspace going through the center of the ε -sphere, with the ε -sphere, results in a halfsphere which is bounded by a great circle. A binary operation of two halfspheres cuts the great circles into great arcs.

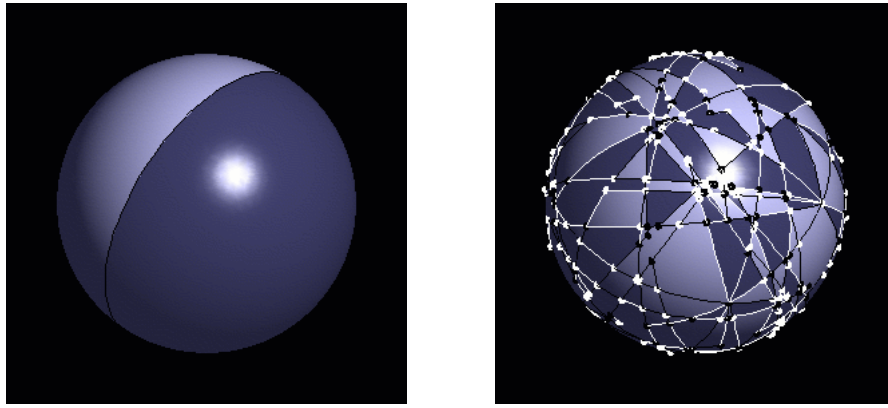

Figure 14.1: Two spherical Nef polyhedra. A closed halfspace on the left and a complex polyhedron on the right. The different colors indicate selected and unselected regions, lines and points.

The incidence structure of planar Nef polyhedra can be reused. The items are denoted as *svertex*, *shalfedge* and *sface*, analogous to their counterparts in *Nef_polyhedron_S2*. Additionally, there is the *shalfloop* representing the great circles. The incidences are illustrated in the figure above.

14.2 Restricted Spherical Geometry

We introduce geometric objects that are part of the spherical surface S_2 and operations on them. We define types *Sphere_point*, *Sphere_circle*, *Sphere_segment*, and *Sphere_direction*. *Sphere_points* are points on S_2 , *Sphere_circles* are oriented great circles of S_2 , *Sphere_segments* are oriented parts of *Sphere_circles* bounded by a pair of *Sphere_points*, and *Sphere_directions* are directions that are part of great circles. (a direction is usually defined to be a vector without length, that floats around in its underlying space and can be used to specify a movement at any point of the underlying space; in our case we use directions only at points that are part of the great circle that underlies also the direction.)

Note that we have to consider special geometric properties of the objects. For example two points that are part of a great circle define two *Sphere_segments*, and two arbitrary *Sphere_segments* can intersect in two points.

If we restrict our geometric objects to a so-called perfect hemisphere of S_2 ¹ then the restricted objects behave like in classical geometry, e.g., two points define exactly one segment, two segments intersect in at most one

¹A perfect hemisphere of S_2 is an open half-sphere plus an open half-circle in the boundary of the open half-sphere plus one endpoint of the half-circle.

interior point (non-degenerately), or three non-cocircular sphere points can be qualified as being positively or negatively oriented.

14.3 Example Programs

14.3.1 First Example

In this first example *Nef_polyhedron_S2* is parametrized with a CGAL Kernel as traits class. The types comprising the spherical geometry can be retrieved from the type *Nef_polyhedron_S2<Traits>* as is done in the example with the type *Sphere_circle*. Then three Nef polyhedra are created: *N1* is a halfsphere including the boundary, *N2* is another halfsphere without the boundary, and *N3* is the intersection of *N1* and *N2*.

```
// examples/Nef_S2/simple.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main()
{
    Nef_polyhedron N1(Sphere_circle(1,0,0));
    Nef_polyhedron N2(Sphere_circle(0,1,0), Nef_polyhedron::EXCLUDED);
    Nef_polyhedron N3 = N1 * N2;
    return 0;
}
```

14.3.2 Construction and Combinations

The example shows the different types of constructors: *N1* is the complete sphere, *N2* is a halfsphere which includes the boundary, *N3* is created with the copy constructor, *N4* is created as an arrangement of a set of *Sphere_segments*, and *N5* is created as the empty set.

The example also shows the use of unary set operations, binary operations, and binary predicates: *N3* is defined as the complement of *N2*, *N1* is compared with the union of *N2* and *N3*, *N5* is united with *N2* and then intersected with *N4*. At last, it is tested if *N5* is a subset of *N2* and if *N5* is not equal to *N4*.

```
// examples/Nef_S2/construction.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
```

```

typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Sphere_point Sphere_point;
typedef Nef_polyhedron::Sphere_segment Sphere_segment;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main() {

    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    Sphere_circle c(1,1,1); // c : x + y + z = 0
    Nef_polyhedron N2(c, Nef_polyhedron::INCLUDED);
    Nef_polyhedron N3(N2.complement());
    CGAL_assertion(N1 == N2.join(N3));

    Sphere_point p1(1,0,0), p2(0,1,0), p3(0,0,1);
    Sphere_segment s1(p1,p2), s2(p2,p3), s3(p3,p1);
    Sphere_segment triangle[3] = { s1, s2, s3 };
    Nef_polyhedron N4(triangle, triangle+3);
    Nef_polyhedron N5;
    N5 += N2;
    N5 = N5.intersection(N4);
    CGAL_assertion(N5 <= N2 && N5 != N4);

    return 0;
}

```

14.3.3 Exploration

By recursively composing binary and unary operations one can end with a very complex rectilinear structure. *Nef_polyhedron_S2* allows read-only exploration of the structure.

In the following example, a random *Nef_polyhedron_S2* *S* created from *n* halfspheres is explored. Each sface is composed of one outer sface cycles and an arbitrary number of inner sfaces cycles. The outer cycle is either an shalfloop or a cycle of shalfedges. An inner cycles additionally can be an isolated vertex. The example shows how to get the entry item *it* to all sface cycles of an sface *sf* and how to find out what type of item it is.

The macro *CGAL_forall_sface_cycles_of* is equivalent to a for-loop on the range [*sf*->*sface_cycles_begin()*, *sf*->*sface_cycles_end()*). An *SFace_cycle_const_iterator* either represents a *SVertex_const_handle*, a *SHalfedge_const_handle* or a *SHalfloop_const_handle*. In order to find out which handle type is represented, the functions *is_svertex()*, *is_shalfedge()* and *is_shalfloop()* are provided. Afterwards the iterator can be casted to the proper handle type.

```

// examples/Nef_S2/exploration.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>

```

```

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;
typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron_S2::SFace_const_iterator SFace_const_iterator;
typedef Nef_polyhedron_S2::SFace_cycle_const_iterator
        SFace_cycle_const_iterator;

int main() {

    Nef_polyhedron_S2 S;
    CGAL::create_random_Nef_S2(S,5);

    int i=0;
    SFace_const_iterator sf;
    CGAL_forall_sfaced(S) {
        SFace_cycle_const_iterator it;
        std::cout << "the sfaced cycles of sfaced " << i++;
        std::cout << " start with an " << std::endl;
        CGAL_forall_sfaced_cycles_of(it,sf) {
            if (it.is_svertex()) {
std::cout << " svertex at position ";
std::cout << SVertex_const_handle(it)->point() << std::endl;
            }
            else if (it.is_shalfedge()) {
std::cout << " shalfedge from ";
std::cout << SHalfedge_const_handle(it)->source()->point() << " to ";
std::cout << SHalfedge_const_handle(it)->target()->point() << std::endl;
            }
            else if (it.is_shalfloop()) {
std::cout << " shalfloop lying in the plane ";
std::cout << SHalfloop_const_handle(it)->circle() << std::endl;
            }
            else
std::cout << "something is wrong" << std::endl;
        }
    }
    return 0;
}

```

14.3.4 Point Location

Using the *locate* function, it is possible to retrieve an item at a certain location on the sphere. In the following example, the item at location *Sphere_point(1,0,0)* in a random *Nef_polyhedron_S2* is retrieved. *locate* returns an instance of type *Object_handle*, which is a container for any handle type. Here, it either a *SVertex_const_handle*, a *SHalfedge_const_handle*, a *SHalfloop_const_handle* or a *SFace_const_handle*. The function *CGAL::assign* performs the cast operation and returns a boolean which indicates whether the cast was successful or not.

```

// examples/Nef_S2/point_location.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;
typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron_S2::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron_S2::Object_handle Object_handle;
typedef Nef_polyhedron_S2::Sphere_point Sphere_point;

int main() {

    Nef_polyhedron_S2 S;
    CGAL::create_random_Nef_S2(S,5);

    SVertex_const_handle sv;
    SHalfedge_const_handle se;
    SHalfloop_const_handle sl;
    SFace_const_handle sf;
    Object_handle o = S.locate(Sphere_point(1,0,0));
    if(CGAL::assign(sv,o))
        std::cout << "Locating svertex" << std::endl;
    else if(CGAL::assign(se,o))
        std::cout << "Locating shalfedge" << std::endl;
    else if(CGAL::assign(sl,o))
        std::cout << "Locating shalfloop" << std::endl;
    else if(CGAL::assign(sf,o))
        std::cout << "Locating sface" << std::endl;
    else {
        std::cout << "something wrong" << std::endl;
        return 1;
    }
    return 0;
}

```

14.3.5 Visualization

Nef_polyhedron_S2 provides an interface for OpenGL visualization via a Qt widget. The usage is shown in the following example:

CGAL::Nef_polyhedron_S2<Traits>

Definition

An instance of data type *Nef_polyhedron_S2<Traits>* is a subset of the sphere S_2 that is the result of forming complements and intersections starting from a finite set H of halfspaces bounded by a plane containing the origin. Halfspaces correspond to hemispheres of S_2 and are therefore modeled by oriented great circles of type *Sphere_circle*. *Nef_polyhedron_S2* is closed under all binary set operations *intersection*, *union*, *difference*, *complement* and under the topological operations *boundary*, *closure*, and *interior*.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

Parameters

```
template < class Nef_polyhedronTraits_S2,
            class Nef_polyhedronItems_S2 = CGAL::SM_items,
            class Nef_polyhedronMarks = bool
class Nef_polyhedron_S2;
```

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple_homogeneous* parametrized with *Gmpz*, *leda_integer* or any other number type modeling \mathbb{Z} , or *Cartesian*, *Simple_cartesian* parametrized with *Gmpq*, *leda_rational*, *Quotient<Gmpz>* or any other number type modeling \mathbb{Q} .

The second parameter and the third parameter are for future considerations. Neither *Nef_polyhedronItems_S2* nor *Nef_polyhedronMarks* is specified, yet. Do not use other than the default types for these two template parameters.

Types

<i>Nef_polyhedron_S2<Traits>::Sphere_point</i>	points in the sphere surface.
<i>Nef_polyhedron_S2<Traits>::Sphere_segment</i>	segments in the sphere surface.
<i>Nef_polyhedron_S2<Traits>::Sphere_circle</i>	oriented great circles modeling spatial half-spaces.

<i>Nef_polyhedron_S2<Traits>::SVertex_const_handle</i>	non-mutable handle to svertex.
<i>Nef_polyhedron_S2<Traits>::SHalfedge_const_handle</i>	non-mutable handle to shalfedge.
<i>Nef_polyhedron_S2<Traits>::SHalfloop_const_handle</i>	non-mutable handle to shalfloop.
<i>Nef_polyhedron_S2<Traits>::SFace_const_handle</i>	non-mutable handle to sface.

<i>Nef_polyhedron_S2<Traits>::SVertex_const_iterator</i>	non-mutable iterator over all svertices.
<i>Nef_polyhedron_S2<Traits>::SHalfedge_const_iterator</i>	non-mutable iterator over all shalfedges.
<i>Nef_polyhedron_S2<Traits>::SHalfloop_const_iterator</i>	non-mutable iterator over all shalfloops.
<i>Nef_polyhedron_S2<Traits>::SFace_const_iterator</i>	non-mutable iterator over all sfaces.

<i>Nef_polyhedron_S2<Traits>::SHalfedge_around_svertex_const_circulator</i>	circulating the adjacency list of an svertex v .
-----------------------------------------------------------------------------------	----------------------------------------------------

Nef_polyhedron_S2<Traits>:: SHalfedge_around_sface_const_circulator

circulating the sface cycle of an sface *f*.

Nef_polyhedron_S2<Traits>:: SFace_cycle_const_iterator

iterating all sface cycles of an sface *f*. The iterator has method *bool is_svertex()*, *bool is_shalfedge()*, *bool is_shalfloop()*, and can be converted to the corresponding handles *SVertex_const_handle*, *SHalfedge_const_handle*, or *SHalfloop_const_handle*.

Nef_polyhedron_S2<Traits>:: Mark

attributes of objects (vertices, edges, faces).

Nef_polyhedron_S2<Traits>:: size_type

size type

enum Boundary { EXCLUDED, INCLUDED};

construction selection.

enum Content { EMPTY, COMPLETE};

construction selection.

Creation

Nef_polyhedron_S2<Traits> N(Content sphere = EMPTY);

creates an instance *N* of type *Nef_polyhedron_S2<K>* and initializes it to the empty set if *sphere == EMPTY* and to the whole sphere if *sphere == COMPLETE*.

Nef_polyhedron_S2<Traits> N(Sphere_circle c, Boundary circle = INCLUDED);

creates a Nef polyhedron *N* containing the half-sphere left of *c* including *c* if *circle == INCLUDED*, excluding *c* if *circle == EXCLUDED*.

template <class Forward_iterator>

Nef_polyhedron_S2<Traits> N(Forward_iterator first,
Forward_iterator beyond,
Boundary b = INCLUDED)

creates a Nef polyhedron *N* from the set of sphere segments in the iterator range *[first,beyond)*. If the set of sphere segments is a simple polygon that separates the sphere surface into two regions, then the polygonal region that is left of the segment **first* is selected. The polygonal region includes its boundary if *b = INCLUDED* and excludes the boundary otherwise. *Forward_iterator* has to be an iterator with value type *Sphere_segment*.

Operations

void N.clear(Content plane = EMPTY)

makes *N* the empty set if *plane == EMPTY* and the full plane if *plane == COMPLETE*.

<i>bool</i>	<i>N.is_empty()</i>	returns true if <i>N</i> is empty, false otherwise.
<i>bool</i>	<i>N.is_sphere()</i>	returns true if <i>N</i> is the whole sphere, false otherwise.

Constructive Operations

<i>Nef_polyhedron_S2<K></i>	<i>N.complement()</i>	returns the complement of <i>N</i> in the plane.
<i>Nef_polyhedron_S2<K></i>	<i>N.interior()</i>	returns the interior of <i>N</i> .
<i>Nef_polyhedron_S2<K></i>	<i>N.closure()</i>	returns the closure of <i>N</i> .
<i>Nef_polyhedron_S2<K></i>	<i>N.boundary()</i>	returns the boundary of <i>N</i> .
<i>Nef_polyhedron_S2<K></i>	<i>N.regularization()</i>	returns the regularized polyhedron (closure of interior).
<i>Nef_polyhedron_S2<K></i>	<i>N.intersection(Nef_polyhedron_S2<K> N1)</i>	returns $N \cap N1$.
<i>Nef_polyhedron_S2<K></i>	<i>N.join(Nef_polyhedron_S2<K> N1)</i>	returns $N \cup N1$.
<i>Nef_polyhedron_S2<K></i>	<i>N.difference(Nef_polyhedron_S2<K> N1)</i>	returns $N - N1$.
<i>Nef_polyhedron_S2<K></i>	<i>N.symmetric_difference(Nef_polyhedron_S2<K> N1)</i>	returns the symmetric difference $N - T \cup T - N$.

Additionally there are operators $*, +, -, \wedge, !$ which implement the binary operations *intersection*, *union*, *difference*, *symmetric difference*, and the unary operation *complement* respectively. There are also the corresponding modification operations $*=, +=, -=, \wedge=$.

There are also comparison operations like $<, <=, >, >=, ==, !=$ which implement the relations subset, subset or equal, superset, superset or equal, equality, inequality, respectively.

Statistics and Integrity

<i>Size_type</i>	<i>N.number_of_svertices()</i>	returns the number of svertices.
<i>Size_type</i>	<i>N.number_of_shalfedges()</i>	returns the number of shalfedges.
<i>Size_type</i>	<i>N.number_of_sedges()</i>	returns the number of sedges.
<i>Size_type</i>	<i>N.number_of_shalfloops()</i>	returns the number of shalfloops.
<i>Size_type</i>	<i>N.number_of_sloops()</i>	returns the number of sloops.

<i>Size_type</i>	<i>N.number_of_sfaced()</i>	returns the number of sfaced.
<i>Size_type</i>	<i>N.number_of_sfaced_cycles()</i>	returns the number of sfaced cycles.
<i>Size_type</i>	<i>N.number_of_connected_components()</i>	
		calculates the number of connected components of <i>P</i> .
<i>void</i>	<i>N.print_statistics(std::ostream& os = std::cout)</i>	
		print the statistics of <i>P</i> : the number of vertices, edges, and faces.
<i>void</i>	<i>N.check_integrity_and_topological_planarity(bool faces=true)</i>	
		checks the link structure and the genus of <i>P</i> .

Exploration - Point location - Ray shooting

As Nef polyhedra are the result of forming complements and intersections starting from a set H of half-spaces that are defined by oriented lines in the plane, they can be represented by an attributed plane map $M = (V, E, F)$. For topological queries within M the following types and operations allow exploration access to this structure.

Types

Nef_polyhedron_S2<Traits>:: Object_handle

a generic handle to an object of the underlying plane map. The kind of object (*vertex*, *halfedge*, *face*) can be determined and the object can be assigned to a corresponding handle by the three functions:

bool assign(Vertex_const_handle& h, Object_handle)

bool assign(Halfedge_const_handle& h, Object_handle)

bool assign(Face_const_handle& h, Object_handle)

where each function returns *true* iff the assignment to *h* was done.

Operations

<i>bool</i>	<i>N.contains(Object_handle h)</i>	
		returns true iff the object <i>h</i> is contained in the set represented by <i>N</i> .

<i>bool</i>	<i>N.contained_in_boundary(Object_handle h)</i>	
		returns true iff the object <i>h</i> is contained in the 1-skeleton of <i>N</i> .

<i>Object_handle</i>	<i>N.locate(Sphere_point p)</i>	
		returns a generic handle <i>h</i> to an object (face, halfedge, vertex) of the underlying plane map that contains the point <i>p</i> in its relative interior. The point <i>p</i> is contained in the set represented by <i>N</i> if <i>N.contains(h)</i> is true. The location mode flag <i>m</i> allows one to choose between different point location strategies.

Object_handle *N.ray_shoot(Sphere_point p, Sphere_direction d)*

returns a handle *h* with *N.contains(h)* that can be converted to a *Vertex_*/*Halfedge_*/*Face_const_handle* as described above. The object returned is intersected by the ray starting in *p* with direction *d* and has minimal distance to *p*. The operation returns the null handle *NULL* if the ray shoot along *d* does not hit any object *h* of *N* with *N.contains(h)*.

Object_handle *N.ray_shoot_to_boundary(Sphere_point p, Sphere_direction d)*

returns a handle *h* that can be converted to a *Vertex_*/*Halfedge_const_handle* as described above. The object returned is part of the 1-skeleton of *N*, intersected by the ray starting in *p* with direction *d* and has minimal distance to *p*. The operation returns the null handle *NULL* if the ray shoot along *d* does not hit any 1-skeleton object *h* of *N*. The location mode flag *m* allows one to choose between different point location strategies.

Iteration

bool *N.has_shalfloop()* returns true iff there is a shalfloop.

SHalfloop_const_handle *N.shalfloop()* returns access to the sloop.

The list of all objects can be accessed via iterator ranges. For comfortable iteration we also provide iterations macros. The iterator range access operations are of the following kind:

SVertex_iterator svertices_begin()/svertices_end()
SHalfedge_iterator shalfedges_begin()/shalfedges_end()
SHalfloop_iterator shalfloops_begin()/shalfloops_end()
SFace_iterator sfaces_begin()/sfaces_end()

The macros are then *CGAL_forall_svertices(v,M)*, *CGAL_forall_shalfedges(e,M)*, *CGAL_forall_sfases(f,M)*, *CGAL_forall_sface_cycles_of(fc,F)* where *M* is a sphere map and *F* is a sface.

Input and Output

A Nef polyhedron *N* can be visualized in an open GL window. The output operator is defined in the file *CGAL/IO/Nef_polyhedron_2_Window_stream.h*.

Implementation

Nef polyhedra are implemented on top of a halfedge data structure and use linear space in the number of vertices, edges and facets. Operations like *empty* take constant time. The operations *clear*, *complement*, *interior*, *closure*, *boundary*, *regularization*, input and output take linear time. All binary set operations and comparison operations take time $O(n \log n)$ where *n* is the size of the output plus the size of the input.

The point location and ray shooting operations are implemented in the naive way. The operations run in linear query time without any preprocessing.

Example

Nef polyhedra are parameterized by a standard CGAL kernel. The example computes the intersection of two Nef polyhedra *N1* and *N2*.

```
// examples/Nef_S2/simple.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main()
{
    Nef_polyhedron N1(Sphere_circle(1,0,0));
    Nef_polyhedron N2(Sphere_circle(0,1,0), Nef_polyhedron::EXCLUDED);
    Nef_polyhedron N3 = N1 * N2;
    return 0;
}
```

CGAL::Nef_polyhedron_S2<Traits>::Sphere_point

Definition

An object p of type *Sphere_point*< R > is a point on the surface of a unit sphere. Such points correspond to the nontrivial directions in space and similarly to the equivalence classes of all nontrivial vectors under normalization.

Types

Sphere_point:: RT ring number type.

Creation

Sphere_point p ; creates some sphere point.

Sphere_point $p(RT\ x, RT\ y, RT\ z)$; creates a sphere point corresponding to the point of intersection of the ray starting at the origin in direction (x, y, z) and the surface of S_2 .

Operations

Access to the coordinates is provided by the following operations. Note that the vector (x, y, z) is not normalized.

RT $p.x()$ the x -coordinate.

RT $p.y()$ the y -coordinate.

RT $p.z()$ the z -coordinate.

$bool$ $p == q$ Equality.

$bool$ $p != q$ Inequality.

Sphere_point $p.antipode()$ returns the antipode of p .

CGAL::Nef_polyhedron_S2<Traits>::Sphere_segment

Definition

An object s of type *Sphere_segment* is a segment in the surface of a unit sphere that is part of a great circle through the origin. Sphere segments are represented by two sphere points p and q plus an oriented plane h that contains p and q . The plane determines the sphere segment as follows. Let c be the circle in the intersection of h and S_2 . Then s is that part of c that is swept, when we rotate p into q in counterclockwise rotation around the normal vector of h as seen from the positive halfspace.

Creation

Sphere_segment s ; creates some sphere segment.

Sphere_segment s (*Sphere_point* $p1$, *Sphere_point* $p2$, *bool* *shorter_arc*=*true*);

creates a spherical segment spanning the shorter arc from $p1$ to $p2$ if *shorter_arc* == *true*. Otherwise the longer arc is created.

Precondition: $p1 \neq p2$ and $p1 \neq p2.opposite()$.

Sphere_segment s (*Sphere_point* $p1$, *Sphere_point* $p2$, *Sphere_circle* c);

creates a spherical segment spanning the arc from $p1$ to $p2$ as part of the oriented circle c ($p1 == p2$ or $p1 == p2.opposite()$ are possible.)

Precondition: $p1$ and $p2$ are contained in c .

Sphere_segment s (*Sphere_circle* $c1$, *Sphere_circle* $c2$);

creates the spherical segment as part of $c1$ that is part of the halfsphere left of the oriented circle $c2$.

Precondition: $c1 \neq c2$ as unoriented circles.

Operations

Sphere_point $s.source()$ the source point of s .

Sphere_point $s.target()$ the target point of s .

Sphere_circle $s.sphere_circle()$ the great circle supporting s .

Sphere_segment $s.opposite()$ returns the spherical segment oriented from $target()$ to $source()$ with the same point set as s .

Sphere_segment $s.complement()$ returns the spherical segment oriented from $target()$ to $source()$ with the point set completing s to a full circle.

<i>bool</i>	<i>s.is_short()</i>	a segment is short iff it is shorter than a half-circle.
<i>bool</i>	<i>s.is_long()</i>	a segment is long iff it is longer than a half-circle.
<i>bool</i>	<i>s.is_degenerate()</i>	return true iff <i>s</i> is degenerate, i.e. source and target are the same.
<i>bool</i>	<i>s.is_halfcircle()</i>	return true iff <i>s</i> is a perfect half-circle, i.e. <i>source().antipode</i> == <i>target()</i> .
<i>bool</i>	<i>s.has_on(Sphere_point p)</i>	 return true iff <i>s</i> contains <i>p</i> .
<i>bool</i>	<i>s.has_in_relative_interior(Sphere_point p)</i>	 return true iff <i>s</i> contains <i>p</i> in its relative interior.

CGAL::Nef_polyhedron_S2<Traits>::Sphere_circle

Definition

An object c of type *Sphere_circle* is an oriented great circle on the surface of a unit sphere. Such circles correspond to the intersection of an oriented plane (that contains the origin) and the surface of S_2 . The orientation of the great circle is that of a counterclockwise walk along the circle as seen from the positive halfspace of the oriented plane.

Types

Sphere_circle::RT ring type.

Sphere_circle::Plane_3 plane a *Sphere_circle* lies in.

Creation

Sphere_circle c ; creates some great circle.

Sphere_circle c (*Sphere_point* p , *Sphere_point* q);

If p and q are opposite of each other, then we create the unique great circle on S_2 which contains p and q . This circle is oriented such that a walk along c meets p just before the shorter segment between p and q . If p and q are opposite of each other then we create any great circle that contains p and q .

Sphere_circle c (*Plane_3* h); creates the circle corresponding to the plane h .
Precondition: h contains the origin.

Sphere_circle c (*RT* x , *RT* y , *RT* z); creates the circle orthogonal to the vector (x, y, z) .

Sphere_circle c (*Sphere_circle* c , *Sphere_point* p);

creates a great circle orthogonal to c that contains p .
Precondition: p is not part of c .

Operations

Sphere_circle c .*opposite()* Returns a sphere circle in the opposite direction of c .

bool c .*has_on*(*Sphere_point* p) returns true iff c contains p .

Plane_3 c .*plane*() returns the plane supporting c .

Sphere_point c .*orthogonal_pole*() returns the point that is the pole of the hemisphere left of c .

Global functions

bool *equal_as_sets(const c1, const c2)*

returns true iff *c1* and *c2* are equal as unoriented circles.

CGAL::Nef_polyhedron_S2<Traits>::SVertex

Definition

The figure on page [1003](#) illustrate the incidence of a svertex on a sphere map.

The member function *out_sedge* returns the first outgoing shalfedge, and *incident_sface* returns the incident sface.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

<i>SVertex:: Mark</i>	type of mark.
<i>SVertex:: Sphere_point</i>	sphere point type stored in SVertex.
<i>SVertex:: SVertex_const_handle</i>	const handle to SVertex.
<i>SVertex:: SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>SVertex:: SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *SVertex* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed svertices internally.

Operations

<i>Mark</i>	<i>e.mark()</i>	the mark of <i>e</i> .
<i>Sphere_point</i>	<i>e.point()</i>	the sphere point of <i>e</i> .
<i>bool</i>	<i>e.is_isolated()</i>	returns —true— if <i>e</i> has no adjacent sedges.
<i>SVertex_const_handle</i>	<i>e.twin()</i>	the twin of <i>e</i> .
<i>SHalfedge_const_handle</i>	<i>e.out_sedge()</i>	the first out sedge of <i>e</i> .
<i>SFace_const_handle</i>	<i>e.incident_sface()</i>	the incident sface of <i>e</i> .

CGAL::Nef_polyhedron_S2<Traits>::SHalfedge

Definition

A shalfedge is a great arc on a sphere map. The figure below depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.

The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se = se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se = se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se = se->cyclic_adj_succ()* can be used as a shortcut.

A const circulator is provided for each of the two circular orders. The circulators are bidirectional and assignable to *SHalfedge_const_handle*.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

<i>SHalfedge:: Mark</i>	type of mark.
<i>SHalfedge:: Sphere_circle</i>	sphere circle type stored in SHalfedge.
<i>SHalfedge:: SVertex_const_handle</i>	const handle to SVertex.
<i>SHalfedge:: SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>SHalfedge:: SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed shalfedges internally.

Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .
<i>SHalfedge_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.source()</i>	the source svertex of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.target()</i>	equals <i>twin()</i> -> <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.sprev()</i>	the SHalfedge previous to <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.snext()</i>	the next SHalfedge of <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_pred()</i>	the edge before <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_succ()</i>	the edge after <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

CGAL::Nef_polyhedron_S2<Traits>::SHalfloop

Definition

A sloop is a great circle on a sphere. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation. Each *Nef_polyhedron_S2* can only have one sloop (resp. two shalfloops).

The figure below depicts the relationship between a shalfloop and sfaces on a sphere map.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

<i>SHalfloop:: Mark</i>	type of mark.
<i>SHalfloop:: Sphere_circle</i>	sphere circle type stored in SHalfloop.
<i>SHalfloop:: SHalfloop_const_handle</i>	const handle to SHalfloop.
<i>SHalfloop:: SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed shalfloops internally.

Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .
<i>SHalfloop_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

CGAL::Nef_polyhedron_S2<Traits>::SFace

Definition

Figure 14.4 on page 1003 and figure 14.4 on page 1005 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface_cycles_begin()/sface_cycles_end()*). Additionally, *Nef_polyhedron_S2* provides the macro *CGAL_forall_sface_cycles_of*. The iterators are of type *SFace_cycle_const_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

<i>SFace:: Mark</i>	type of mark.
<i>SFace:: Object_list</i>	list of Object handles.
<i>SFace:: Vertex_const_handle</i>	const handle to Vertex.
<i>SFace:: Volume_const_handle</i>	const handle to Volume.
<i>SFace:: SFace_const_handle</i>	const handle to SFace.
<i>SFace:: SFace_cycle_const_iterator</i>	const iterator over the entries to all sface cycles of a sface.

Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed sfaces internally.

Operations

<i>Mark</i>	<i>sf.mark()</i>	the mark of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_begin()</i>	iterator over the entries to all sface cycles of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_S2<Traits>::SFace_cycle_iterator

Definition

The type *SFace_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SVertex_handle*, *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_svertex()*, *is_shalfedge()* and *is_shalfloop()* are provided.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

Types

<i>SFace_cycle_iterator::SVertex_handle</i>	const handle to <i>SVertex</i> .
<i>SFace_cycle_iterator::SHalfedge_handle</i>	const handle to <i>SHalfedge</i> .
<i>SFace_cycle_iterator::SHalfloop_handle</i>	const handle to <i>SHalfloop</i> .

Creation

<i>SFace_cycle_iterator sfc;</i>	default constructor.
----------------------------------	----------------------

Operations

<i>bool</i>	<i>sfc.is_svertex()</i>	returns true if <i>sfc</i> represents a <i>SVertex_handle</i> .
<i>bool</i>	<i>sfc.is_shalfedge()</i>	returns true if <i>sfc</i> represents a <i>SHalfedge_handle</i> .
<i>bool</i>	<i>sfc.is_shalfloop()</i>	returns true if <i>sfc</i> represents a <i>SHalfloop_handle</i> .
<i>SVertex_handle</i>	<i>SVertex_handle(sfc)</i>	casts <i>sfc</i> to <i>SVertex_handle</i> .
<i>SHalfedge_handle</i>	<i>SHalfedge_handle(sfc)</i>	casts <i>sfc</i> to <i>SHalfedge_handle</i> .
<i>SHalfloop_handle</i>	<i>SHalfloop_handle(sfc)</i>	casts <i>sfc</i> to <i>SHalfloop_handle</i> .

CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>

Definition

The class *Qt_widget_Nef_S2* uses the OpenGL interface of Qt in order to display a *Nef_polyhedron_S2*. Its purpose is to provide an easy to use viewer for *Nef_polyhedron_S2*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *QGLWidget*, *Qt_widget_Nef_S2* only has a single public constructor. For the usage of *Qt_widget_Nef_S2* see the example below.

```
#include <CGAL/IO/Qt_widget_Nef_S2.h>
```

Parameters

The template parameter expects an instantiation of *Nef_polyhedron_S2<Traits>*.

Creation

```
Qt_widget_Nef_S2<Nef_polyhedron_S2> W( Nef_polyhedron_S2 N);
```

Creates a widget *W* for displaying the *Nef_polyhedron_S2* *N*.

See Also

CGAL::Nef_polyhedron_S2<Traits> page [991](#)

Example

This example create some random *Sphere_segments* and distributes them on two *Nef_polyhedron_2*. The two Nef polyhedra are combined by a symmetric difference and the result is displayed in a Qt widget.

15.1 Introduction

In solid modeling, two major representation schemes are used: *constructive solid geometry* (CSG) and *boundary representations* (B-rep). Both have inherent strengths and weaknesses, see [Hof89c] for a discussion.

In CSG a solid is represented as a set-theoretic boolean combination of primitive solid objects, such as blocks, prisms, cylinders, or toruses. The boolean operations are not evaluated, instead, objects are represented implicitly with a tree structure; leaves represent primitive objects and interior nodes represent boolean operations or rigid motions, e.g., translation and rotation. Algorithms on such a CSG-tree first evaluate properties on the primitive objects and propagate the results using the tree structure.

A B-rep describes the incidence structure and the geometric properties of all lower-dimensional features of the boundary of a solid. Surfaces are oriented to decide between the interior and exterior of a solid.

The class of representable objects in a CSG is usually limited by the choice of the primitive solids. A B-rep is usually limited by the choice for the geometry of the supporting curves for edges and the supporting surfaces for surface patches, and, in addition, the connectivity structure that is allowed. In particular, a B-rep is not always closed under boolean set operations. As an example, the class of orientable 2-manifold objects is a popular and well understood class of surfaces commonly used for B-reps. They can be represented and manipulated efficiently, the data structures are compact in storage size, and many algorithms are simple. On the other side, this object class is not closed under boolean set operations, as many examples can illustrate, such as the Figure shown above that can be generated using boolean set operations on cubes. The vertices bounding the tunnel, or the edge connecting the “roof” with the cube are non-manifold situations.

In our implementation of Nef polyhedra in 3D, we offer a B-rep data structure that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations (see Section 15.4 for an explanation of regularized set operations). In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL-based visualizer for debugging and illustrations.

15.2 Definition

The theory of Nef polyhedra has been developed for arbitrary dimensions. The class `CGAL::Nef_polyhedron_3` implements a boundary representation for the 3-dimensional case.

Definition: A *Nef-polyhedron* in dimension d is a point set $P \subseteq \mathbb{R}^d$ generated from a finite number of open halfspaces by set complement and set intersection operations.

Set union, difference and symmetric difference can be reduced to intersection and complement. Set complement changes between open and closed halfspaces, thus the topological operations *boundary*, *interior*, *exterior*, *closure* and *regularization* are also in the modeling space of Nef polyhedra.

A face of a Nef polyhedron is defined as an equivalence class of *local pyramids* that are a characterization of the local space around a point.

Definition: A point set $K \subseteq \mathbb{R}^d$ is called a *cone with apex 0*, if $K = \mathbb{R}^+ K$ (i.e., $\forall p \in K, \forall \lambda > 0 : \lambda p \in K$) and it is called a *cone with apex x* , $x \in \mathbb{R}^d$, if $K = x + \mathbb{R}^+(K - x)$. A cone K is called a *pyramid* if K is a polyhedron.

Now let $P \in \mathbb{R}^d$ be a polyhedron and $x \in \mathbb{R}^d$. There is a neighborhood $U_0(x)$ of x such that the pyramid

$Q := x + \mathbb{R}^+((P \cap U(x)) - x)$ is the same for all neighborhoods $U(x) \subseteq U_0(x)$. Q is called the *local pyramid* of P in x and denoted $\text{Pyr}_P(x)$.

Definition: Let $P \in \mathbb{R}^d$ be a polyhedron and $x, y \in \mathbb{R}^d$ be two points. We define an equivalence relation $x \sim y$ iff $\text{Pyr}_P(x) = \text{Pyr}_P(y)$. The equivalence classes of \sim are the *faces* of P . The dimension of a face s is the dimension of its affine hull, $\dim s := \dim \text{aff } s$.

In other words, a *face* s of P is a maximal non-empty subset of \mathbb{R}^d such that all of its points have the same local pyramid Q denoted $\text{Pyr}_P(s)$. This definition of a face partitions \mathbb{R}^d into faces of different dimension. A face s is either a subset of P , or disjoint from P . We use this later in our data structure and store a selection mark in each face indicating its set membership.

Faces do not have to be connected. There are only two full-dimensional faces possible, one whose local pyramid is the space \mathbb{R}^d itself and the other with the empty set as a local pyramid. All lower-dimensional faces form the *boundary* of the polyhedron. As usual, we call zero-dimensional faces *vertices* and one-dimensional faces *edges*. In the case of polyhedra in space we call two-dimensional faces *facets* and the full-dimensional faces *volumes*. Faces are *relative open* sets, e.g., an edge does not contain its end-vertices.

We illustrate the definitions with an example in the plane. Given the closed halfspaces

$$h_1 : y \geq 0, \quad h_2 : x - y \geq 0, \quad h_3 : x + y \leq 3, \quad h_4 : x - y \geq 1, \quad h_5 : x + y \leq 2,$$

we define our polyhedron $P := (h_1 \cap h_2 \cap h_3) - (h_4 \cap h_5)$.

The left figure illustrates the polyhedron with its partially closed and partially open boundary, i.e., vertex v_4, v_5, v_6 , and edges e_4 and e_5 are not part of P . The local pyramids for the faces are $\text{Pyr}_P(f_1) = \emptyset$ and $\text{Pyr}_P(f_2) = \mathbb{R}^2$. Examples for the local pyramids of edges are the closed halfspace h_2 for the edge e_1 , $\text{Pyr}_P(e_1) = h_2$, and the open halfspace that is the complement of h_4 for the edge e_5 , $\text{Pyr}_P(e_5) = \{(x, y) | x - y < 1\}$. The edge e_3 consists actually of two disconnected parts, both with the same local pyramid $\text{Pyr}_P(e_3) = h_1$. In our data structure, we will represent the two connected components of the edge e_3 separately. The figure on the right lists all local pyramids for this example.

The local pyramids of each vertex are represented by conceptually intersecting the local neighborhood with a small ε -sphere. This intersection forms a planar map on the sphere (see next two figures), which together with the set-selection mark for each item (i.e. vertices, edges, loops and faces) forms a two-dimensional Nef polyhedron embedded in the sphere. We add the set-selection mark for the vertex and call the resulting structure the *sphere map* of the vertex. We use the prefix s to distinguish the elements of the sphere map from the three-dimensional elements. See Chapter 14 for further details.

Having sphere maps for all vertices of our polyhedron is a sufficient but not easily accessible representation of the polyhedron. We enrich the data structure with more explicit representations of all the faces and incidences between them.

We depart slightly from the definition of faces in a Nef polyhedron; we represent the connected components of a face individually and do not implement additional bookkeeping to recover the original faces (e.g., all edges on a common supporting line with the same local pyramid) as this is not needed in our algorithms. We discuss features in the increasing order of dimension.

edges: We store two oppositely oriented edges for each edge and have a pointer from one oriented edge to its opposite edge. Such an oriented edge can be identified with an *svertex* in a sphere map; it remains to link one *svertex* with the corresponding opposite *svertex* in the other sphere map.

edge uses: An edge can have many incident facets (non-manifold situation). We introduce two oppositely oriented edge-uses for each incident facet; one for each orientation of the facet. An edge-use points to its corresponding oriented edge and to its oriented facet. We can identify an edge-use with an oriented *sedge* in the sphere map, or, in the special case also with an *sloop*. Without mentioning it explicitly in the remainder, all references to *sedge* can also refer to *sloop*.

facets: We store oriented facets as boundary cycles of oriented edge-uses. We have a distinguished outer boundary cycle and several (or maybe none) inner boundary cycles representing holes in the facet. Boundary cycles are linked in one direction. We can access the other traversal direction when we switch to the oppositely oriented facet, i.e., by using the opposite edge-use.

shells: The volume boundary decomposes into different connected components, the *shells*. A shell consists of a connected set of facets, edges, and vertices incident to this volume. Facets around an edge form a radial order that is captured in the radial order of *sedges* around an *svertex* in the sphere map. Using this information, we can trace a shell from one entry element with a graph search. We offer this graph traversal (to the user) in a visitor design pattern.

volumes: A volume is defined by a set of shells, one outer shell containing the volume and several (or maybe none) inner shells separating voids which are excluded from the volume.

For each face we store a label, e.g., a set-selection mark, which indicates whether the face is part of the solid or if it is excluded. We call the resulting data structure *Selective Nef Complex*, *SNC* for short [GHH⁺03]. However, in CGAL we identify the names and call the *SNC* data structure *CGAL::Nef_polyhedron_3*.

15.3 Infimaximal Box

We call a Nef polyhedron *bounded* if its boundary is bounded, i.e., finite, and *unbounded* otherwise. Note that unbounded point sets can have a bounded boundary, for example, the complement of a cube has an unbounded outer volume, but its boundary remains bounded.

Using a boundary representation, it is convenient (conceptually and in our implementation) to consider bounded Nef polyhedra only. Bounded Nef polyhedra are also closed under boolean set operations. However, one needs to start with bounded primitives; the conceptually nice halfspaces cannot be used. Instead, we offer a construction from oriented 2-manifolds represented in a *CGAL::Polyhedron*, see Section 15.5.4 below.

In order to handle unbounded Nef polyhedra conceptually in the same way as we handle bounded Nef polyhedra, we intersect them with a bounding cubical volume of size $[-R, R]^3$, where R is a symbolical unspecified value, which is finite but larger than all coordinate values that may occur in the bounded part of the polyhedron. As a result, each Nef polyhedron becomes bounded. We call the boundary of the bounding volume the *infimaximal box* [SM00].

We clip lines and rays at the infimaximal box. The intersection points with the infimaximal box are called *non-standard points*, which are points whose coordinates are $-R$ or R in at least one dimension, and linear functions $f(R)$ for the other dimensions. Such extended points (and developed from there also extended segments etc) are provided in CGAL with extended kernels—*CGAL::Extended_cartesian* and *CGAL::Extended_homogeneous*. They are regular CGAL kernels with a polynomial type as coordinate number type.

As long as an extended kernel is used, the full functionality provided by the *CGAL::Nef_polyhedron_3* class is available. If a kernel that does not use polynomials to represent coordinates is used, it is not possible to create or load unbounded Nef polyhedra, but all other operations work as expected. We provided both possibilities, since the restriction to bounded Nef polyhedra improves considerably space requirements (plain number type instead of polynomial), and runtime performance.

15.4 Regularized Set Operations

Since manifolds are not closed under boolean operations, Requicha proposes to use *regularized set operations* [KM76, Req80]. A set is *regular*, if it equals the closure of its interior. A regularized set operation is defined as the standard set operation followed by a regularization of the result. Regularized sets are closed under regularized set operations.

Regularized set operations are important since they simplify the class of solids to exclude lower dimensional features and the boundary belongs to the point set. These properties are considered to reflect the nature of physical solids more closely.

Regularized polyhedral sets are a subclass of Nef polyhedra. We provide the *regularization* operation as a shortcut for the consecutive execution of the *interior* and the *closure* operations.

15.5 Example Programs

The following example gives a first impression of how to instantiate and use *Nef_polyhedron_3*. We use the *CGAL::Cartesian* kernel. All Cartesian and homogeneous kernels of CGAL are suitable if the number type parameter follows the usual requirements of being a model of the *CGAL::FieldNumberType* concept for the Cartesian kernels, or the *CGAL::RingNumberType* concept for the homogeneous kernels, respectively. Note however, that in the current state, the Nef polyhedron works only with CGAL kernels. The implementation makes use of CGAL specific functions in kernel objects, and does not yet offer a designed interface to a clean kernel concept that could be offered by an external kernel as well.

The example creates two Nef polyhedra—*N0* is the empty set, while *N1* represents the full space, i.e., the set of all points in the 3-dimensional space. The assertion assures that the empty set is the complement of the full space.

```
// file: examples/Nef_3/simple.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {
    Nef_polyhedron N0(Nef_polyhedron::EMPTY);
    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    CGAL_assertion (N0 == N1.complement());
    return 0;
}
```

15.5.1 Construction and Comparison

This example shows the various constructors. We can create the empty set, which is also the default constructor, and the full space, i.e. all points of \mathbb{R}^3 belong to the polyhedron. We can create a halfspace defined by a plane bounding it. It is only available if an extended kernel is used. The halfspace constructor has a second parameter that specifies whether the defining plane belongs to the point set (*Nef_polyhedron::INCLUDED*) or not (*Nef_polyhedron::EXCLUDED*). The default value is *Nef_polyhedron::INCLUDED*. Additionally, we can create a *Nef_polyhedron_3* from a *Polyhedron_3*, see the Section 15.5.4 below.

We can compute the point sets of two Nef polyhedra for equality and proper subset relationships. We offer the usual comparison operators `==`, `!=`, `<=`, `>=`, `<` and `>`.

Nef polyhedra have the important feature that a representation that is called the *reduced Würzburg structure* is unique, i.e., two point sets of Nef polyhedra are equal if and only if the representations are equal. The proof for the reduced Würzburg structure carries over to our representation and the comparison operators are therefore trivial to implement.

```
// file: examples/Nef_3/construction.C

#include <CGAL/Gmpz.h>
```

```

#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Plane_3 Plane_3;

int main() {
    Nef_polyhedron N0;
    Nef_polyhedron N1(Nef_polyhedron::EMPTY);
    Nef_polyhedron N2(Nef_polyhedron::COMPLETE);
    Nef_polyhedron N3(Plane_3( 1, 2, 5,-1));
    Nef_polyhedron N4(Plane_3( 1, 2, 5,-1), Nef_polyhedron::INCLUDED);
    Nef_polyhedron N5(Plane_3( 1, 2, 5,-1), Nef_polyhedron::EXCLUDED);

    CGAL_assertion(N0 == N1);
    CGAL_assertion(N3 == N4);
    CGAL_assertion(N0 != N2);
    CGAL_assertion(N3 != N5);

    CGAL_assertion(N4 >= N5);
    CGAL_assertion(N5 <= N4);
    CGAL_assertion(N4 > N5);
    CGAL_assertion(N5 < N4);

    N5 = N5.closure();
    CGAL_assertion(N4 >= N5);
    CGAL_assertion(N4 <= N5);

    return 0;
}

```

15.5.2 Point Set Operations

As explained in the introduction, Nef polyhedra are closed under all boolean set operations. The class *Nef_polyhedron_3* provides functions and operators for the most common ones: complement (*operator!*), union (*operator+*), difference (*operator-*), intersection (*operator**) and symmetric difference (*operator^*). Additionally, the operators **=*, *-=*, **=* and *^=* are defined.

Nef_polyhedron_3 also provides the topological operations *interior()*, *closure()* and *boundary()*. With *interior()* one deselects all boundary items, with *boundary()* one deselects all volumes, and with *closure()* one selects all boundary items.

```

// file: examples/Nef_3/point_set_operations.C

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Plane_3 Plane_3;

```

```

int main() {

    Nef_polyhedron N1(Plane_3( 1, 0, 0,-1));
    Nef_polyhedron N2(Plane_3(-1, 0, 0,-1));
    Nef_polyhedron N3(Plane_3( 0, 1, 0,-1));
    Nef_polyhedron N4(Plane_3( 0,-1, 0,-1));
    Nef_polyhedron N5(Plane_3( 0, 0, 1,-1));
    Nef_polyhedron N6(Plane_3( 0, 0,-1,-1));

    Nef_polyhedron I1(!N1 + !N2); // open slice in yz-plane
    Nef_polyhedron I2(N3 - !N4); // closed slice in xz-plane
    Nef_polyhedron I3(N5 ^ N6); // open slice in yz-plane
    Nef_polyhedron Cube1(I2 * !I1);
    Cube1 *= !I3;
    Nef_polyhedron Cube2 = N1 * N2 * N3 * N4 * N5 * N6;

    CGAL_assertion(Cube1 == Cube2); // both are closed cube
    CGAL_assertion(Cube1 == Cube1.closure());
    CGAL_assertion(Cube1 == Cube1.regularization());
    CGAL_assertion((N1 - N1.boundary()) == N1.interior());
    CGAL_assertion(I1.closure() == I1.complement().interior().complement());
    CGAL_assertion(I1.regularization() == I1.interior().closure());
    return 0;
}

```

15.5.3 Transformation

Using the *std::transform* function, a Nef polyhedron can be translated, rotated and scaled. The usage is shown in the following example:

```

// examples/Nef_3/transformation.C

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Plane_3 Plane_3;
typedef Nef_polyhedron::Vector_3 Vector_3;
typedef Nef_polyhedron::Aff_transformation_3 Aff_transformation_3;

int main() {

    Nef_polyhedron N(Plane_3(0,1,0,0));
    Aff_transformation_3 transl(CGAL::TRANSLATION, Vector_3(5, 7, 9));
    Aff_transformation_3 rotx90(1,0,0,
        0,0,-1,
        0,1,0,
        1);
}

```

```

Aff_transformation_3 scale(3,0,0,
    0,3,0,
    0,0,3,
    2);

N.transform(transl);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0,1,0,-7)));
N.transform(rotx90);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0,0,1,-7)));
N.transform(scale);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0,0,2,-21)));

return 0;
}

```

15.5.4 The Interface between *Polyhedron_3* and *Nef_polyhedron_3*

Nef_polyhedron_3 provides an interface for the conversion between polyhedral surfaces represented with the *CGAL::Polyhedron_3* class and *Nef_polyhedron_3*. *Polyhedron_3* represents orientable 2-manifold objects with boundaries. However, we exclude surfaces with boundaries from the conversion to *Nef_polyhedron_3* since they have no properly defined volume.

Both conversion directions can only be performed if the boundary of the point set is an oriented closed 2-manifold. *Nef_polyhedron_3* provides the function *is_simple()* and *Polyhedron_3* provides the function *is_closed()* to test for this property. The usage is illustrated by the example program below.

The conversion gives us the possibility to use several file formats. *Polyhedron_3* can read the (.off) file format and can write the (.off), OpenInventor (.iv), VRML 1.0 and 2.0 (.wrl) and Wavefront Advanced Visualizer object format (.obj), see Section 10.4.

```

// file: examples/Nef_3/interface_polyhedron.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <iostream>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Vector_3 Vector_3;
typedef Kernel::Aff_transformation_3 Aff_transformation_3;

int main() {
    Polyhedron P;
    std::cin >> P;
    if(P.is_closed()) {
        Nef_polyhedron N1(P);
        Nef_polyhedron N2(N1);
    }
}

```

```

Aff_transformation_3 aff(CGAL::TRANSLATION, Vector_3(2,2,0,1));
N2.transform(aff);
N1 += N2;

if(N1.is_simple()) {
    N1.convert_to_Polyhedron(P);
    std::cout << P;
}
else
    std::cerr << "N1 is not a 2-manifold." << std::endl;
}
}

```

15.5.5 Using an Extended Kernel

The provided extended kernels are used the same way as any other CGAL kernel. The essential difference is, that coordinates are not represented by the number type that was used to parameterize the kernel type, but by a *Nef_polynomial* parametrized by that number type.

The example iterates all vertices of a given Nef polyhedron and decides whether it is an standard vertex or a vertex on the infimal box. Furthermore, it tests whether any of the vertices is at (R, R, R) . Recall that R was the symbolical value, large but finite, for the size of the infimal box.

```

// file: examples/Nef_3/extended_kernel.C

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Gmpz NT;
typedef CGAL::Extended_homogeneous<NT> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::RT RT;
typedef Nef_polyhedron::Point_3 Point_3;
typedef Nef_polyhedron::Plane_3 Plane_3;
typedef Nef_polyhedron::Vertex_const_iterator Vertex_const_iterator;

int main() {

    Nef_polyhedron N;
    std::cin >> N;

    Vertex_const_iterator v;
    for(v = N.vertices_begin(); v != N.vertices_end(); ++v) {
        Point_3 p(v->point());
        if(p.hx().degree() > 0 || p.hy().degree() > 0 || p.hz().degree() > 0)
            std::cout << "extended vertex at " << p << std::endl;
        else
            std::cout << "standard vertex at " << p << std::endl;

        if(p == Point_3(RT(0,1), RT(0,1), RT(0,1)))

```

```

        std::cout << "    found vertex (right,back,top) of the infimaximal box"
                    << std::endl;
    }

    return 0;
}

```

15.6 File I/O

Nef_polyhedron_3 provides an input and an output operator for a proprietary file format. It includes the complete incidence structure, the geometric data, and the marks of each item. The output depends on the output operators of the geometric primitives provided by the traits class, and on the output operators of the used number type. Therefore, it is necessary to use the same kernel and the same number type for input and output operations.

We recommend to use the CGAL kernels *Homogeneous*, *Simple_homogeneous*, or *Extended_homogeneous*. We provide compatibility between the input and output of these kernels. Especially, it is possible to write a bounded Nef polyhedron using the *Extended_homogeneous* kernel and to read it afterwards using one of the two others.

Using CGAL stream modifiers the following output formats can be chosen: *ASCII*(*set_ascii_mode*), *binary*(*set_binary_mode*) or *pretty*(*set_pretty_mode*). The mandatory format is the ASCII format.

```

// file: examples/Nef_3/nefIO.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <fstream>

typedef CGAL::Gmpz NT;
typedef CGAL::Homogeneous<NT> SK;
typedef CGAL::Extended_homogeneous<NT> EK;
typedef CGAL::Nef_polyhedron_3<SK> Nef_polyhedron_S;
typedef CGAL::Nef_polyhedron_3<EK> Nef_polyhedron_E;

int main() {
    Nef_polyhedron_E E;
    Nef_polyhedron_S S;

    std::cin >> E;

    if(E.is_bounded()) {
        std::ofstream out("temp.nef3");
        out << E;
        std::ifstream in("temp.nef3");
        in >> S;
    }
}

```

15.7 Further Example Programs

15.7.1 Exploring a Sphere Map

A sphere map is explored by using the function *get_sphere_map*, which returns the sphere map of the specified vertex as a *Nef_polyhedron_S2*. *Nef_polyhedron_S2* provides the functionality necessary for the exploration. Note, that one has to use the type *Nef_polyhedron_S2* as specified in *Nef_polyhedron_3* as is shown in the following example.

```
// file: examples/Nef_3/exploration_SM.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main() {

    // We've put the typedefs here as VC7 gives us an ICE if they are global typedefs
    typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
    typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;
    typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
    typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
    typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
    typedef Nef_polyhedron_S2::SFace_const_iterator SFace_const_iterator;
    typedef Nef_polyhedron_S2::SFace_cycle_const_iterator
        SFace_cycle_const_iterator;

    Nef_polyhedron_3 N;
    std::cin >> N;

    Vertex_const_iterator v = N.vertices_begin();
    Nef_polyhedron_S2 S(N.get_sphere_map(v));

    int i=0;
    SFace_const_iterator sf;
    for(sf = S.sfaces_begin(); sf != S.sfaces_end(); sf++) {
        SFace_cycle_const_iterator it;
        std::cout << "the sface cycles of sface " << i++ << " start with an\n";
        for(it = sf->sface_cycles_begin(); it != sf->sface_cycles_end(); it++) {
            if (it.is_svertex())

15.7.2 Exploring Shells

A *shell* of a Nef polyhedron is the connected part of the surface incident to a certain volume. Each halffacet, sface and shalfedge belongs to a single shell. The figure below illustrates the notion of a shell. It shows a Nef polyhedron with two volumes and three shells.

The first volume is the outer volume and the second volume is the interior of the cube. The first shell is the whole surface of the left object. The second shell is the outer surface of the right object, and the third shell is the inner surface of the right object.

In detail, the first shell consists of two halffacets, eight halfedges and four vertices. The second shell consists of the eight vertices of the cube plus the two endpoints of the antenna, all halffacets oriented outwards, and all halfedges. The third shell consists of the same eight vertices of the cube, plus the endpoint of the antenna that is in contact with the cube, all halffacets oriented inwards, and all halfedges (the same as for the second shell).

We discuss how sfaces, shalfedges, and sloops belong to the shells with a closeup view of the situation at the antenna foot. As you can see, there are three items on the sphere map - a shalfloop for each halffacet which intersects the sphere, and an svertex where the antenna intersects the sphere. The upper shalfloop lies on the halffacet which is oriented outwards and is therefore also oriented outwards. This shalfloop and the svertex

belong to the second shell. The other shalfloop lies on the inwards oriented halfacet and is oriented inwards, too. This shalfloop belongs to the third shell.

Nef_polyhedron_3 offers a visitor interface to explore a shell following the well-known visitor pattern [GHJV95]. The interface is illustrated by the following example.

```
// file: examples/Nef_3/shell_exploration.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Vertex_const_handle Vertex_const_handle;
typedef Nef_polyhedron::Halfedge_const_handle Halfedge_const_handle;
typedef Nef_polyhedron::Halfacet_const_handle Halfacet_const_handle;
typedef Nef_polyhedron::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron::Volume_const_iterator Volume_const_iterator;
typedef Nef_polyhedron::Shell_entry_const_iterator Shell_entry_const_iterator;
typedef Kernel::Point_3 Point_3;

class Shell_explorer {
    bool first;
    const Nef_polyhedron& N;
    Vertex_const_handle v_min;

public:
    Shell_explorer(const Nef_polyhedron& N_)
        : first(true), N(N_) {}

    void visit(Vertex_const_handle v) {
        if(first || CGAL::lexicographically_xyz_smaller(v->point(), v_min->point())) {
            v_min = v;
            first=false;
        }
    }

    void visit(Halfedge_const_handle e) {}
    void visit(Halfacet_const_handle f) {}
    void visit(SHalfedge_const_handle se) {}
    void visit(SHalfloop_const_handle sl) {}
    void visit(SFace_const_handle sf) {}

    Vertex_const_handle& minimal_vertex() { return v_min; }
    void reset_minimal_vertex() { first = true; }
};

int main() {
    Nef_polyhedron N;
    std::cin >> N;
```

```

int ic = 0;
Volume_const_iterator c;
Shell_explorer SE(N);
CGAL_forall_volumes(c,N) {
    std::cout << "Volume " << ic++ << std::endl;
    int is = 0;
    Shell_entry_const_iterator it;
    CGAL_forall_shells_of(it,c) {
        SE.reset_minimal_vertex();
        N.visit_shell_objects(SFace_const_handle(it),SE);
        Point_3 p(SE.minimal_vertex()->point());
        std::cout << "  minimal vertex of shell " << is++
                    << " is at " << p << std::endl;
    }
}
}

```

The function *visit_shell_objects*(*SFace_const_handle sf*, *Visitor& V*) explores a shell starting at the *sf*. The second argument expects any class providing the (possibly empty) functions *visit(Vertex_const_handle)*, *visit(Halfedge_const_handle)* (remember that *Halfedge* is the same type as *SVertex*), *visit(Halfacet_const_handle)*, *visit(SHalfedge_const_handle)*, *visit(SHalfloop_const_handle)* and *visit(SFace_const_handle)*. The *visit_shell_objects* function will call *visit* for each item belonging to the shell once. There are no further requirements on that class.

In the example, the class *Shell_explorer* is passed as second argument to *visit_shell_objects*. Its task is to find the lexicographically smallest vertex of a shell. Its internal state consists of three variables. The first one is a reference to the explored Nef polyhedron. This reference is often necessary to retrieve information from the Nef polyhedron. The second variable *v_min* stores the smallest vertex found so far, and the third variable *first* is initialized to *false* to signal that no vertex has been visited so far. After the first vertex has been visited *first* is changed to *true*.

Shell_explorer provides further member functions. After the exploration of a shell the *minimal_vertex* function retrieves the smallest vertex. The *reset_minimal_vertex* function allows one to use the same instance of *Shell_explorer* on multiple shells. In this case, the *reset_minimal_vertex* function has to be called between the exploration of two shells.

The example program uses the *Shell_explorer* for each shell of the given Nef polyhedron once and reports the smallest vertex of each shell to the standard output.

15.7.3 Point Location

The *locate(Point_3 p)* function locates the point *p* in the Nef polyhedron and returns the item the point belongs to. The *locate* function returns an instance of *Object_handle*, which is a polymorphic handle type representing any handle type, no matter if it is mutable or const. For further usage of the result, the *Object_handle* has to be casted to the concrete handle type. The *CGAL::assign* function performs such a cast. It returns a boolean that reports the success or the failure of the cast. Looking at the possible return values of the *locate* function, the *Object_handle* can represent a *Vertex_const_handle*, a *Halfedge_const_handle*, a *Halfacet_handle*, or a *Volume_const_handle*. One of the four casts will succeed.

```
// file: examples/Nef_3/point_location.C
```

```

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;
    typedef Kernel::Point_3 Point_3;

int main() {
    //We've put the typedefs here as VC7 gives us an ICE if they are global typedefs
    typedef Nef_polyhedron_3::Vertex_const_handle Vertex_const_handle;
    typedef Nef_polyhedron_3::Halfedge_const_handle Halfedge_const_handle;
    typedef Nef_polyhedron_3::Halfacet_const_handle Halfacet_const_handle;
    typedef Nef_polyhedron_3::Volume_const_handle Volume_const_handle;
    typedef Nef_polyhedron_3::Object_handle Object_handle;

    Nef_polyhedron_3 N;
    std::cin >> N;

    Vertex_const_handle v;
    Halfedge_const_handle e;
    Halfacet_const_handle f;
    Volume_const_handle c;
    Object_handle o = N.locate(Point_3(0,0,0));
    if(CGAL::assign(v,o))
        std::cout << "Locating vertex" << std::endl;
    else if(CGAL::assign(e,o))
        std::cout << "Locating edge" << std::endl;
    else if(CGAL::assign(f,o))
        std::cout << "Locating facet" << std::endl;
    else if(CGAL::assign(c,o))
        std::cout << "Locating volume" << std::endl;
    //other cases can not occur

    return 0;
}

```

15.8 Visualization

With the *Qt_widget_OpenGL* class an interface to OpenGL visualization via Qt is offered. The class knows how to handle mouse movements and clicks and how to move and scale the 3D object displayed in the widget. *Qt_widget_OpenGL* is a basis for writing Qt widgets displaying 3D objects. A user can derive a new class from *Qt_widget_OpenGL* which implements the drawing method and configures the context menus.

15.8.1 Visualizing a 3D Nef polyhedron

Qt_widget_Nef_3 implements the drawing methods for displaying instances of *Nef_polyhedron_3*. The following example shows how to set up a QApplication with a main widget of type *Qt_widget_Nef_3* and how to start the viewer.

#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
```

```

typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {
    Nef_polyhedron_3 N;
    std::cin >> N;

    QApplication a(argc, argv);
    CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>* w =
        new CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>(N);
    a.setMainWidget(w);
    w->show();
    return a.exec();
}
#endif

```

15.8.2 Visualizing a Sphere Map

Qt_widget_Nef_S2 is a widget implemented on the basis of *Qt_widget_OpenGL*. It can be used to visualize the sphere map of a vertex in a *Nef_polyhedron_3* using the interface between *Nef_polyhedron_S2* and *Nef_polyhedron_3*.

3D Boolean Operations on Nef Polyhedra

Reference Manual

Peter Hachenberger, Lutz Kettner, and Michael Seel

A Nef polyhedron is any point set generated from a finite number of open halfspaces by set complement and set intersection operations. In our implementation of Nef polyhedra in 3-dimensional space, we offer a B-rep data structures that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations. In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL visualization for debugging and illustrations.

CGAL::Nef_polyhedron_3<Traits>

Definition

A 3D Nef polyhedron is a subset of the 3-dimensional space that is the result of forming complements and intersections starting from a finite set H of 3-dimensional halfspaces. Nef polyhedra are closed under all binary set operations, i.e., intersection, union, difference, complement, and under the topological operations boundary, closure, and interior.

A 3D Nef polyhedron can be represented by the local pyramids of the minimal elements of its incidence structure. Without going into too much detail, a local pyramid essentially reflects the topologic and geometric situation at a certain location in a point set. For finite polyhedra the minimal elements of the incidence structure are vertices only. This means, that it suffices to model the topological and geometric situation of the vertices. For 3D Nef polyhedra, the local pyramid of a vertex is represented by a planar Nef polyhedra embedded on a sphere.

A *Nef_polyhedron_3* consists of vertices V , a sphere map for each vertex in V , edges E , facets F , volumes C , a mark for every item, and an incidence relation on them. Each edge and each facet is represented by two halfedges or two halffacets, respectively.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Parameters

```
template < class Nef_polyhedronTraits_3,
            class Nef_polyhedronItems_3 = CGAL::SNC_items,
            class Nef_polyhedronMarks = bool >
class Nef_polyhedron_3;
```

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple_homogeneous*, *Extended_homogeneous_3* parametrized with *Gmpz*, *leda_integer* or any other number type modeling \mathbb{Z} , or *Cartesian*, *Simple_cartesian*, *Extended_cartesian_3* parametrized with *Gmpq*, *leda_rational*, *Quotient<Gmpz>* or any other number type modeling \mathbb{Q} .

The second parameter and the third parameter are for future considerations. Neither *Nef_polyhedronItems_3* nor *Nef_polyhedronMarks* is specified, yet. Do not use any other than the default types for these two template parameters.

Types

<i>Nef_polyhedron_3<Traits>:: Traits</i>	traits class selected for <i>Nef_polyhedronTraits_3</i> .
<i>Nef_polyhedron_3<Traits>:: Mark</i>	All object (vertices, edges, etc.) are attributed by a Mark. Mark equals bool.
<i>Nef_polyhedron_3<Traits>:: size_type</i>	size type of <i>Nef_polyhedron_3</i> .
<i>Nef_polyhedron_3<Traits>:: Vertex_const_handle</i>	non-mutable handle to a vertex.
<i>Nef_polyhedron_3<Traits>:: Halfedge_const_handle</i>	non-mutable handle to a halfedge.
<i>Nef_polyhedron_3<Traits>:: Halffacet_const_handle</i>	non-mutable handle to a halffacet.

<i>Nef_polyhedron_3<Traits>:: Volume_const_handle</i>	non-mutable handle to a volume.
<i>Nef_polyhedron_3<Traits>:: SVertex_const_handle</i>	non-mutable handle to a svertex.
<i>Nef_polyhedron_3<Traits>:: SHalfedge_const_handle</i>	non-mutable handle to a shalfedge.
<i>Nef_polyhedron_3<Traits>:: SHalfloop_const_handle</i>	non-mutable handle to a shalfloop.
<i>Nef_polyhedron_3<Traits>:: SFace_const_handle</i>	non-mutable handle to a sface.
<i>Nef_polyhedron_3<Traits>:: Vertex_const_iterator</i>	non-mutable iterator over all vertices.
<i>Nef_polyhedron_3<Traits>:: Halfedge_const_iterator</i>	non-mutable iterator over all halfedges.
<i>Nef_polyhedron_3<Traits>:: Halffacet_const_iterator</i>	non-mutable iterator over all halffacets.
<i>Nef_polyhedron_3<Traits>:: Volume_const_iterator</i>	non-mutable iterator over all volumes.
<i>Nef_polyhedron_3<Traits>:: SVertex_const_iterator</i>	non-mutable iterator over all svertices.
<i>Nef_polyhedron_3<Traits>:: SHalfedge_const_iterator</i>	non-mutable iterator over all shalfedges.
<i>Nef_polyhedron_3<Traits>:: SHalfloop_const_iterator</i>	non-mutable iterator over all shalfloops.
<i>Nef_polyhedron_3<Traits>:: SFace_const_iterator</i>	non-mutable iterator over all sfaces.
<i>Nef_polyhedron_3<Traits>:: SHalfedge_around_svertex_const_circulator</i>	
	non-mutable circulator of shalfedges around a svertex (cw).
<i>Nef_polyhedron_3<Traits>:: SHalfedge_around_sface_const_circulator</i>	
	non-mutable circulator of shalfedges around a sface (ccw).
<i>Nef_polyhedron_3<Traits>:: SHalfedge_around_facet_const_circulator</i>	
	non-mutable circulator of shalfedges around a halffacet (ccw).
<i>Nef_polyhedron_3<Traits>:: SFace_cycle_const_iterator</i>	
	non-mutable iterator over the cycles of a sface.
<i>Nef_polyhedron_3<Traits>:: Halffacet_cycle_const_iterator</i>	
	non-mutable iterator over the cycles of a halffacet.
<i>Nef_polyhedron_3<Traits>:: Shell_entry_const_iterator</i>	
	non-mutable iterator providing an entry to each shell.
<i>Nef_polyhedron_3<Traits>:: Object_handle</i>	a generic handle to an object. The kind of object (<i>vertex</i> , <i>halfedge</i> , <i>halffacet</i> , <i>volume</i> , <i>svertex</i> , <i>shalfedge</i> , <i>shalfloop</i> , <i>sface</i>) can be determined and the object can be assigned to a corresponding constant handle by one of the following functions: <i>bool assign(Vertex_const_handle& h, Object_handle)</i> <i>bool assign(Halfedge_const_handle& h, Object_handle)</i> <i>bool assign(Halffacet_const_handle& h, Object_handle)</i> <i>bool assign(Volume_const_handle& h, Object_handle)</i> <i>bool assign(SVertex_const_handle& h, Object_handle)</i> <i>bool assign(SHalfedge_const_handle& h, Object_handle)</i> <i>bool assign(SHalfloop_const_handle& h, Object_handle)</i> <i>bool assign(SFace_const_handle& h, Object_handle)</i> where each function returns <i>true</i> iff the assignment to <i>h</i> could be accomplished.
<i>Nef_polyhedron_3<Traits>:: Point_3</i>	location of vertices.

<i>Nef_polyhedron_3<Traits>:: Segment_3</i>	segment represented by a halfedge.
<i>Nef_polyhedron_3<Traits>:: Vector_3</i>	direction of a halfedge.
<i>Nef_polyhedron_3<Traits>:: Plane_3</i>	plane of a halffacet lies in.
<i>Nef_polyhedron_3<Traits>:: Aff_transformation_3</i>	affine transformation.

enum Boundary { EXCLUDED, INCLUDED};

construction selection.

enum Content { EMPTY, COMPLETE};

construction selection.

Nef_polyhedron_3<Traits>:: Nef_polyhedron_S2

a sphere map.

Nef_polyhedron_3<Traits>:: Polyhedron

a polyhedral surface.

Creation

Nef_polyhedron_3<Traits> N(Content space = EMPTY);

creates a Nef polyhedron and initializes it to the empty set if *plane == EMPTY* and to the whole space if *space == COMPLETE*.

Nef_polyhedron_3<Traits> N(Plane_3 p, Boundary b = INCLUDED);

creates a Nef polyhedron containing the halfspace left of *p* including *p* if *b==INCLUDED*, excluding *p* if *b==EXCLUDED*.

Nef_polyhedron_3<Traits> N(Polyhedron& P);

creates a Nef polyhedron, which represents the same point set as the polyhedral surface *P* does.

Nef_polyhedron_3<Traits> N(Input_iterator begin, Input_iterator end);

creates a Nef polyhedron consisting of a single polygon spanned by the list of points in the iterator range *[begin,end)*. If the points do not on a common supporting plane, the constructor tries to triangulate the polygon into multiple facets.If the construction does not succeed, the empty set is created.

Access Member Functions

<i>bool</i>	<i>N.is_simple()</i>	returns true, if <i>N</i> is a 2-manifold.
<i>bool</i>	<i>N.is_valid()</i>	checks the integrity of <i>N</i> .
<i>Size_type</i>	<i>N.number_of_vertices()</i>	returns the number of vertices.

<i>Size_type</i>	<i>N.number_of_halfedges()</i>	return the number of halfedges.
<i>Size_type</i>	<i>N.number_of_edges()</i>	returns the number of halfedge pairs.
<i>Size_type</i>	<i>N.number_of_halffacets()</i>	returns the number of halffacets.
<i>Size_type</i>	<i>N.number_of_facets()</i>	returns the number of halffacet pairs.
<i>Size_type</i>	<i>N.number_of_volumes()</i>	returns the number of volumes.

<i>Vertex_const_iterator</i>	<i>N.vertices_begin()</i>	iterator over all vertices.
<i>Vertex_const_iterator</i>	<i>N.vertices_end()</i>	past-the-end iterator.

<i>Halfedge_const_iterator</i>	<i>N.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_const_iterator</i>	<i>N.halfedges_end()</i>	past-the-end iterator.

<i>Halffacet_const_iterator</i>	<i>N.halffacets_begin()</i>	iterator over all halffacets.
<i>Halffacet_const_iterator</i>	<i>N.halffacets_end()</i>	past-the-end iterator.

<i>Volume_const_iterator</i>	<i>N.volumes_begin()</i>	iterator over all volumes.
<i>Volume_const_iterator</i>	<i>N.volumes_end()</i>	past-the-end iterator.

The following macros are provided: *CGAL_forall_vertices(v,N)*, *CGAL_forall_halfedges(e,N)*, *CGAL_forall_edges(e,N)*, *CGAL_forall_halffacets(f,N)*, *CGAL_forall_facets(f,N)*, *CGAL_forall_volumes(c,N)* where *N* is a *Nef_polyhedron_3*.

<i>Object_handle</i>	<i>N.locate(Point_3 p)</i>	returns a generic handle to the object (vertex, edge, facet or volume) which contains the point p in its relative interior.
----------------------	-----------------------------	-----------------------------------------------------------------------------------------------------------------------------

<i>Nef_polyhedron_S2</i>	<i>N.get_sphere_map(Vertex_const_iterator v)</i>	returns the neighborhood of a vertex modeled by a <i>Nef_polyhedron_S2</i> .
--------------------------	---------------------------------------------------	------------------------------------------------------------------------------

Point Set Predicates

<i>bool</i>	<i>N.is_empty()</i>	returns true, if <i>N</i> is the empty point set.
<i>bool</i>	<i>N.is_space()</i>	returns true, if <i>N</i> is the complete 3D space.
<i>bool</i>	<i>N == N1</i>	returns true, if <i>N</i> and <i>N1</i> comprise the same point sets.
<i>bool</i>	<i>N != N1</i>	returns true, if <i>N</i> and <i>N1</i> comprise different point sets.
<i>bool</i>	<i>N < N1</i>	returns true, if <i>N</i> is a proper subset of <i>N1</i> .
<i>bool</i>	<i>N > N1</i>	returns true, if <i>N</i> is a proper superset of <i>N1</i> .
<i>bool</i>	<i>N <= N1</i>	returns true, if <i>N</i> is a subset of <i>N1</i> .
<i>bool</i>	<i>N >= N1</i>	returns true, if <i>N</i> is a superset of <i>N1</i> .

Unary Set Operations

<i>Nef_polyhedron_3<Traits></i>	<i>N.complement()</i>	returns the complement of <i>N</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N.interior()</i>	returns the interior of <i>N</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N.boundary()</i>	returns the boundary of <i>N</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N.closure()</i>	returns the closure of <i>N</i> .

<i>Nef_polyhedron_3<Traits></i>	<i>N.regularization()</i>	returns the regularization, i.e. the closure of the interior, of <i>N</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>!N</i>	returns the complement of <i>N</i> .

Binary Set Operations

<i>Nef_polyhedron_3<Traits></i>	<i>N.intersection(N1)</i>	return the intersection of <i>N</i> and <i>N1</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N.join(N1)</i>	return the union of <i>N</i> and <i>N1</i> . (Note that "union" is a C++ keyword and cannot be used for this operation.)
<i>Nef_polyhedron_3<Traits></i>	<i>N.difference(N1)</i>	return the difference between <i>N</i> and <i>N1</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N.symmetric_difference(N1)</i>	return the symmetric difference of <i>N</i> and <i>N1</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N * N1</i>	return the intersection of <i>N</i> and <i>N1</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N + N1</i>	return the union of <i>N</i> and <i>N1</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N - N1</i>	return the difference between <i>N</i> and <i>N1</i> .
<i>Nef_polyhedron_3<Traits></i>	<i>N ^ N1</i>	return the symmetric difference of <i>N</i> and <i>N1</i> .
<i>void</i>	<i>N *= N1</i>	intersects <i>N</i> and <i>N1</i> .
<i>void</i>	<i>N += N1</i>	unites <i>N</i> with <i>N1</i> .
<i>void</i>	<i>N -= N1</i>	subtracts <i>N1</i> from <i>N</i> .
<i>void</i>	<i>N ^= N1</i>	performs a symmetric intersection of <i>N</i> and <i>N1</i> .

Operations

<i>void</i>	<i>N.clear(Content space = EMPTY)</i>	make <i>N</i> the empty set if <i>space == EMPTY</i> and the complete 3D space if <i>space == COMPLETE</i> .
<i>void</i>	<i>N.transform(Aff_transformation_3 aff)</i>	applies an affine transformation to <i>N</i> .
<i>void</i>	<i>N.convert_to_Polyhedron(Polyhedron& P)</i>	converts <i>N</i> into a Polyhedron. Precondition: <i>N</i> is simple.
<i>void</i>	<i>N.visit_shell_objects(SFace_const_handle f, Visitor& V)</i>	calls the visit function of <i>V</i> for every item which belongs to the same shell as <i>sf</i> .

Example

This example program creates two Nef polyhedra - one representing the empty point set, one representing the whole 3D space. The complement of the latter one is computed and compared with the first one.

```
// file: examples/Nef_3/simple.C

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {
    Nef_polyhedron N0(Nef_polyhedron::EMPTY);
    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    CGAL_assertion (N0 == N1.complement());
    return 0;
}
```

CGAL::Nef_polyhedron_3<Traits>::Vertex

Definition

A vertex is a point in the 3-dimensional space. Its incidence structure can be accessed creating a sphere map of the vertex. This is done by the member function *get_sphere_map* of the class *Nef_polyhedron_3*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

Vertex::Mark type of mark.

Vertex::Point_3 point type stored in Vertex.

Creation

There is no need for a user to create a *Vertex* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed vertices internally.

Operations

Mark *v.mark()* the mark of *v* .

Point_3 *v.point()* the point of *v* .

CGAL::Nef_polyhedron_S2<Traits> page [991](#)

CGAL::Nef_polyhedron_3<Traits>::Halfedge

Definition

A Halfedge has a double meaning. In the global incidence structure of a *Nef_polyhedron_3* it is an oriented edge going from one vertex to another. A halfedge also coincides with an svertex of the sphere map of its source vertex. Because of this, we offer the types *Halfedge* and *SVertex* which are the same. Furthermore, the redundant functions *center_vertex()* and *source()* are provided. The reason is, that we get the same vertex either if we want to have the source vertex of a halfedge, or if we want to have the vertex in the center of the sphere map a svertex lies on. Figure 15.9 on page 1045 and figure 15.9 on page 1042 illustrate the incidence of a svertex on a sphere map and of a halfedge in the global structure.

As part of the global incidence structure, the member functions *source* and *target* return the source and target vertex of an edge. The member function *twin()* returns the opposite halfedge.

Looking at the incidence structure on a sphere map, the member function *out_sedge* returns the first outgoing halfedge, and *incident_sface* returns the incident sface.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>Halfedge::Mark</i>	type of mark.
<i>Halfedge::Sphere_point</i>	sphere point type stored in Halfedge.
<i>Halfedge::Vertex_const_handle</i>	const handle to vertex.
<i>Halfedge::Halfedge_const_handle</i>	const handle to halfedge.
<i>Halfedge::SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>Halfedge::SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *Halfedge* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed halfedges internally.

Operations

<i>Mark</i>	<i>e.mark()</i>	the mark of <i>e</i> .
<i>Sphere_point</i>	<i>e.point()</i>	the sphere point of <i>e</i> .
<i>bool</i>	<i>e.is_isolated()</i>	returns —true— if <i>e</i> has no adjacent sedges.
<i>Vertex_const_handle</i>	<i>e.center_vertex()</i>	the center vertex of the sphere map <i>e</i> belongs to.

<i>Vertex_const_handle</i>	<i>e.source()</i>	the source vertex of <i>e</i> .
<i>Vertex_const_handle</i>	<i>e.target()</i>	the target vertex <i>e</i> .
<i>Halfedge_const_handle</i>	<i>e.twin()</i>	the twin of <i>e</i> .
<i>SHalfedge_const_handle</i>		
	<i>e.out_sedge()</i>	the first out sedege of <i>e</i> .
<i>SFace_const_handle</i>	<i>e.incident_sface()</i>	the incident sface of <i>e</i> .

CGAL::Nef_polyhedron_3<Traits>::Halffacet

Definition

A halffacet is an oriented, rectilinear bounded part of a plane. The following figure depicts the incidences to halfedges, vertices and the notion of facet cycles.

The member function *twin* returns the opposite halffacet, *incident_volume* returns the incident volume. A Halffacet cycle either consists of consecutive halfedges along the border (or a hole) of the halffacet, or of a single shalloop on the sphere map of a vertex isolated on the halffacet. The iterator range (*halffacet_cycles_begin()/halffacet_cycles_end()*) provides an entry element for each halffacet cycle of a halffacet.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>Halffacet:: Mark</i>	type of mark.
<i>Halffacet:: Plane_3</i>	plane type stored in Halffacet.
<i>Halffacet:: Object_list</i>	list of Object handles.
<i>Halffacet:: Halffacet_const_handle</i>	const handle to Halffacet.
<i>Halffacet:: Volume_const_handle</i>	const handle to volume.
<i>Halffacet:: Halffacet_cycle_const_iterator</i>	const iterator over the entries to all halffacet cycles of a halffacet.

Creation

There is no need for a user to create a *Halffacet* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed halffacets internally.

Operations

<i>Mark</i>	<i>f.mark()</i>	the mark of <i>f</i> .
<i>Plane_3</i>	<i>f.plane()</i>	the supporting plane of <i>f</i> .
<i>Halffacet_const_handle</i>	<i>f.twin()</i>	the twin of <i>f</i> .
<i>Volume_const_handle</i>	<i>f.incident_volume()</i>	the incident volume of <i>f</i> .
<i>Halffacet_cycle_const_iterator</i>	<i>f.facet_cycle_begin()</i>	iterator over the entries to all halffacet cycles of <i>f</i> .
<i>Halffacet_cycle_const_iterator</i>	<i>f.facet_cycle_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::Volume

Definition

A volume is a full-dimensional connected point set in \mathbb{R}^3 . It is bounded by several shells, i.e. a connected part of the boundary incident to a single volume. An entry element to each shell is provided by the iterator range (*shells_begin()/shells_end()*). A *Shell_entry_iterator* is assignable to *SFace_handle*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>Volume:: Mark</i>	type of mark.
<i>Volume:: Object_list</i>	list of Object handles.
<i>Volume:: Volume_const_handle</i>	const handle to Volume.
<i>Volume:: Shell_entry_const_iterator</i>	const iterator over the entries to all shells adjacent to a volume.

Creation

There is no need for a user to create a *Volume* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed volumes internally.

Operations

<i>Mark</i>	<i>c.mark()</i>	the mark of <i>c</i> .
<i>Shell_entry_const_iterator</i>	<i>c.shells_begin()</i>	const iterator over the entries to all shells adjacent to <i>c</i> .
<i>Shell_entry_const_iterator</i>	<i>c.shells_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::SHalfedge

Definition

A shalfedge is a great arc on a sphere map. Figure 15.9 on page 1045 depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.

The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se = se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se = se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se = se->cyclic_adj_succ()* can be used as a shortcut.

The role of shalfedges in a facet is illustrated in Figure 15.9 on page 1042. The *facet()* member function returns the facet in which the shalfedge is part of one of the facet cycles. The successive assignment of the form *se = se->next()* cycles counterclockwise around the facet (or a hole of the facet).

A const circulators is provided for each of the three circular orders. The circulators are bidirectional and assignable to *SHalfedge_const_handle*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

SHalfedge::Mark type of mark.

SHalfedge::Sphere_circle sphere circle type stored in SHalfedge.

SHalfedge::Halfacet_const_handle const handle to Halfacet.

SHalfedge::SVertex_const_handle const handle to SVertex.

SHalfedge::SHalfedge_const_handle const handle to SHalfedge.

SHalfedge::SFace_const_handle const handle to SFace.

Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed shalfedges internally.

Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .
<i>SHalfedge_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.source()</i>	the source svertex of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.target()</i>	equals <i>twin()</i> -> <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.prev()</i>	the SHalfedge previous to <i>se</i> in a facet cycle.
<i>SHalfedge_const_handle</i>	<i>se.next()</i>	the next SHalfedge of <i>se</i> in a facet cycle.
<i>SHalfedge_const_handle</i>	<i>se.sprev()</i>	the SHalfedge previous to <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.snext()</i>	the next SHalfedge of <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_pred()</i>	the edge before <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_succ()</i>	the edge after <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>Halffacet_const_handle</i>	<i>se.facet()</i>	the facet that corresponds to <i>se</i> in the 3D incidence structure.
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

CGAL::Nef_polyhedron_3<Traits>::SHalfloop

Definition

A shalfloop is a great circle on a sphere map. Figure 15.9 on page 1047 depicts the relationship between a shalfloop and its incident shalfloops, and sfaces on a sphere map. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation.

A sphere map having a shalfloop models the neighborhood of a vertex which is isolated on a facet. That facet is returned by the member function *facet*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>SHalfloop:: Mark</i>	type of mark.
<i>SHalfloop:: Sphere_circle</i>	sphere circle type stored in SHalfloop.
<i>SHalfloop:: Halffacet_const_handle</i>	const handle to Halffacet.
<i>SHalfloop:: SHalfloop_const_handle</i>	const handle to SHalfloop.
<i>SHalfloop:: SFace_const_handle</i>	const handle to SFace.

Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed shalfloops internally.

Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .

<i>SHalfloop_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>Halffacet_const_handle</i>	<i>se.facet()</i>	the facet that corresponds to <i>se</i> in the 3D incidence structure.
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

CGAL::Nef_polyhedron_3<Traits>::SFace

Definition

Figure 15.9 on page 1045 and figure 15.9 on page 1047 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface_cycles_begin()/sface_cycles_end()*). Additionally, *Nef_polyhedron_S2* provides the macro *CGAL_forall_sface_cycles_of*. The iterators are of type *SFace_cycle_const_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

<i>SFace:: Mark</i>	type of mark.
<i>SFace:: Object_list</i>	list of Object handles.
<i>SFace:: Vertex_const_handle</i>	const handle to Vertex.
<i>SFace:: Volume_const_handle</i>	const handle to Volume.
<i>SFace:: SFace_const_handle</i>	const handle to SFace.
<i>SFace:: SFace_cycle_const_iterator</i>	const iterator over the entries to all sface cycles of a sface.

Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed sfaces internally.

Operations

<i>Mark</i>	<i>sf.mark()</i>	the mark of <i>sf</i> .
<i>Vertex_const_handle</i>	<i>sf.center_vertex()</i>	the center vertex of the sphere map <i>sf</i> belongs to.
<i>Volume_const_handle</i>	<i>sf.volume()</i>	the volume that corresponds to <i>sf</i> in the 3D incidence structure.
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_begin()</i>	iterator over the entries to all sface cycles of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_end()</i>	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::Halffacet_cycle_iterator

Definition

The type *Halffacet_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_shalfedge()* and *is_shalfloop()* are provided.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

<i>Halffacet_cycle_iterator::SHalfedge_handle</i>	const handle to <i>SHalfedge</i> .
<i>Halffacet_cycle_iterator::SHalfloop_handle</i>	const handle to <i>SHalfloop</i> .

Creation

<i>Halffacet_cycle_iterator hfc;</i>	default constructor.
--------------------------------------	----------------------

Operations

<i>bool</i>	<i>hfc.is_shalfedge()</i>	returns true if <i>hfc</i> represents a <i>SHalfedge_handle</i> .
<i>bool</i>	<i>hfc.is_shalfloop()</i>	returns true if <i>hfc</i> represents a <i>SHalfloop_handle</i> .
<i>SHalfedge_handle</i>	<i>SHalfedge_handle(hfc)</i>	casts <i>hfc</i> to <i>SHalfedge_handle</i> .
<i>SHalfloop_handle</i>	<i>SHalfloop_handle(hfc)</i>	casts <i>hfc</i> to <i>SHalfloop_handle</i> .

CGAL::Nef_polyhedron_3<Traits>::SFace_cycle_iterator

Definition

The type *SFace_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SVertex_handle*, *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_svertex()*, *is_shalfedge()* and *is_shalfloop()* are provided.

```
#include <CGAL/Nef_polyhedron_3.h>
```

Types

<i>SFace_cycle_iterator::SVertex_handle</i>	const handle to <i>SVertex</i> .
<i>SFace_cycle_iterator::SHalfedge_handle</i>	const handle to <i>SHalfedge</i> .
<i>SFace_cycle_iterator::SHalfloop_handle</i>	const handle to <i>SHalfloop</i> .

Creation

<i>SFace_cycle_iterator sfc;</i>	default constructor.
----------------------------------	----------------------

Operations

<i>bool</i>	<i>sfc.is_svertex()</i>	returns true if <i>sfc</i> represents a <i>SVertex_handle</i> .
<i>bool</i>	<i>sfc.is_shalfedge()</i>	returns true if <i>sfc</i> represents a <i>SHalfedge_handle</i> .
<i>bool</i>	<i>sfc.is_shalfloop()</i>	returns true if <i>sfc</i> represents a <i>SHalfloop_handle</i> .
<i>SVertex_handle</i>	<i>SVertex_handle(sfc)</i>	casts <i>sfc</i> to <i>SVertex_handle</i> .
<i>SHalfedge_handle</i>	<i>SHalfedge_handle(sfc)</i>	casts <i>sfc</i> to <i>SHalfedge_handle</i> .
<i>SHalfloop_handle</i>	<i>SHalfloop_handle(sfc)</i>	casts <i>sfc</i> to <i>SHalfloop_handle</i> .

CGAL::OFF_to_nef_3

Definition

This constructor creates a 3D Nef polyhedron from OFF file. OFF file is read from input stream *in*. The purpose of *OFF_to_nef_3* is to create a Nef polyhedron from an OFF file that cannot be handled by the *Nef_polyhedron_3* constructors. It handles double coordinates while using a homogenous kernel, non-coplanar facets, surfaces with boundaries, self-intersecting surfaces, and single facets. Every closed volume gets marked. The function returns the number of facets it could not handle.

```
template<class Nef_polyhedron_3>
std::size_t      OFF_to_nef_3( std::istream& in, Nef_polyhedron_3& N)
```

See Also

CGAL::Nef_polyhedron_3<Traits> page [1033](#)

CGAL::operator<<

Definition

This operator writes The Nef polyhedron N to the output stream *out* using a propriatary file format. It includes the complete incidence structure, the geometric data, and the marks of each item.

Using CGAL stream modifiers the following output formats can be chosen: ASCII(*set_ascii_mode*), binary(*set_binary_mode*) or pretty(*set_pretty_mode*). The mandatory format is the ASCII format. It is recommended to use this format for file input and output.

As the output depends on the output operators of the geometric primitives provided by the traits class, it might not be possible that the input operator and output operators of different traits classes are not compatible. We recommend to use the CGAL kernels *Homogeneous*, *Simple_homogeneous*, or *Extended_homogeneous* parametrized with any exact number type that models *mathbb{Z}* (e.g. *Gmpz* or *leda_integer*).

A bounded *Nef_polyhedron_3*<*Extended_homogeneous*> is automatically written as though *Nef_polyhedron_3*<*CGAL::Homogeneous*> or *Nef_polyhedron_3*<*CGAL::Simple_homogeneous*> is used. As a result, the input operator of each of these types can read the output.

```
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
```

```
template <class Nef_polyhedronTraits_3>
ostream& ostream& out << CGAL::Nef_polyhedron_3<Nef_polyhedronTraits_3> N
```

See Also

CGAL::Nef_polyhedron_3<*Traits*> page [1033](#)
operator>> page [1054](#)

CGAL::operator>>

Definition

This operator reads a Nef polyhedron, which is given in the proprietary file format written by the input operator *in* and assigns it to *N*. It includes the complete incidence structure, the geometric data, and the marks of each item.

It is recommended to use the CGAL kernels *Homogeneous*, *Simple_homogeneous*, or *Extended_homogeneous* parametrized with any exact number type that models \mathbb{Z} (e.g. *Gmpz* or *leda_integer*). The input and output iterators of Nef polyhedra parametrized with either of these kernels are compatible as long as the Nef polyhedron is bounded. An unbounded Nef polyhedron can only be read by a Nef polyhedron parametrized with an extended kernel. It is also recommended to use the CGAL stream modifier *set_ascii_mode*.

The input operator and output operators of N

```
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
```

```
template <class Nef_polyhedronTraits_3>

CGAL::Qt_widget_Nef_3<Nef_polyhedron_3

Definition

The class *Qt_widget_Nef_3* uses the OpenGL interface of Qt to display a *Nef_polyhedron_3*. Its purpose is to provide an easy to use viewer for *Nef_polyhedron_3*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *OpenGLWidget* via, *Qt_widget_Nef_3* only has a single public constructor. For the usage of *Qt_widget_Nef_3* see the example below.

```
#include <CGAL/IO/Qt_widget_Nef_3.h>
```

Parameters

The template parameter expects an instantiation of *Nef_polyhedron_3<Traits>*.

Creation

```
Qt_widget_Nef_3<Nef_polyhedron_3> W( Nef_polyhedron_3 N);
```

Creates a widget *W* for displaying the 3D Nef polyhedron *N*.

See Also

CGAL::Nef_polyhedron_3<Traits> page [1033](#)

Example

This example reads a 3D Nef polyhedron from standard input and displays it in a Qt widget.

16.1 Definitions

16.1.1 2D Contour

A *2D contour* is a closed sequence (a cycle) of 3 or more *connected 2D oriented straight line segments* called *contour edges*. The endpoints of the contour edges are called *vertices*. Each contour edge shares its endpoints with at least two other contour edges.

If the edges intersect only at the vertices and at most are coincident along a line but do not *cross* one another, the contour is classified as *simple*.

A contour is topologically equivalent to a *disk* and if it is simple, is said to be a *Jordan Curve*.

Contours partition the plane in two open regions: one bounded and one unbounded. If the bounded region of a contour is a *singly-connected set*, the contour is said to be *strictly-simple*.

The *Orientation* of a contour is given by the order of the vertices around the region they bound. It can be *Clockwise* (CCW) or *Counter-clockwise* (CW).

The *bounded side* of a contour edge is the side facing the bounded region of the contour. If the contour is oriented CCW, the bounded side of an edge is its left side.

A contour with a null edge (a segment of length zero given by two consecutive coincident vertices), or with edges not connected to the bounded region (an antenna: 2 consecutive edges going forth and back along the same line), is said to be *degenerate* (collinear edges are *not* considered a degeneracy).

16.1.2 2D Polygon with Holes

A 2D *polygon* is a contour.

A 2D *polygon with holes* is a contour, called the *outer contour*, having zero or more contours, called *inner contours*, or *holes*, in its bounded region. The intersection of the bounded region of the outer contour and the unbounded regions of each inner contour is the *interior* of the polygon with holes. The orientation of the holes must be opposite to the orientation of the outer contour and there cannot be any intersection among any contour. A hole cannot be in the bounded region of any other hole.

A polygon with holes is strictly-simple if its interior is a singly-connected set.

The orientation of a polygon with holes is the orientation of its outer contour. The bounded side of *any* edge, whether of the outer contour or a hole, is the *same* for all edges. That is, if the outer contour is oriented CCW and the holes CW, both contour and hole edges face the polygon interior to their left.

Throughout the rest of this chapter the term *polygon* will be used as a shortcut for *polygon with holes*.

Figure 16.1: Examples of strictly simple polygons: One with no holes and two edges coincident (left) and one with 2 holes (right).

16.1.3 Inward Offset of a Non-degenerate Strictly-Simple Polygon with Holes

For any 2D non-degenerate strictly-simple polygon with holes called the *source*, there can exist a *set* of 0, 1 or more *inward offset polygons with holes*, or just offset polygons for short, at some euclidean distance $t > 0$

Figure 16.2: Examples of non-simple polygons: One folding into itself, that is, non-planar (left), one with a vertex touching an edge (right), and one with a hole crossing into the outside (bottom)

(each being strictly simple and non-degenerate). Any contour edge of such offset polygon, called an *offset edge* corresponds to *some* contour edge of the source polygon, called its *source edge*. An offset edge is parallel to its source edge and has the same orientation. The Euclidean distance between the *lines* supporting an offset edge and its source edge is exactly t .

An offset edge is always located to the bounded side of its source edge (which is an oriented straight line segment).

An offset polygon can have less, equal or more sides as its source polygon.

If the source polygon has no holes, no offset polygon has holes. If the source polygon has holes, any of the offset polygons can have holes itself, but it might as well have no holes at all (if the distance is sufficiently large).

Each offset polygon has the same orientation as the source polygon.

16.1.4 Straight Skeleton of a 2D Non-degenerate Strictly-Simple Polygon with Holes

The *2D straight skeleton* of a non-degenerate strictly-simple polygon with holes [AAAG95] is a special partitioning of the polygon interior into *straight skeleton regions* corresponding to the monotone areas traced by a continuous *inward offsetting* of the contour edges. Each region corresponds to exactly 1 contour edge.

These regions are bounded by angular bisectors of the supporting lines of the contour edges and each such region is itself a non-convex non-degenerate strictly-simple polygon.

Angular Bisecting Lines and Offset Bisectors

Given two points and a line passing through them, the perpendicular line passing through the midpoint is the bisecting line (or bisector) of those points.

Figure 16.3: Offset contours of a sample polygon

Two non-parallel lines, intersecting at a point, are bisected by two other lines passing through that intersection point.

Two parallel lines are bisected by another parallel line placed halfway in between.

Given just one line, any perpendicular line can be considered the bisecting line (any bisector of any two points along the single line).

The bisecting lines of two edges are the lines bisecting the supporting lines of the edges (if the edges are parallel or collinear, there is just one bisecting line).

The halfplane to the bounded side of the line supporting a contour edge is called the *offset zone* of the contour edge.

Given any number of contour edges (not necessarily consecutive), the intersection of their offset zones is called their *combined offset zone*.

Any two contour edges define an *offset bisector*, as follows: If the edges are non-parallel, their bisecting lines can be decomposed as 4 rays originating at the intersection of the supporting lines. Only one of these rays is contained in the combined offset zone of the edges (which one depends on the possible combinations of orientations). This ray is the offset bisector of the non-parallel contour edges.

If the edges are parallel (but not collinear) and have opposite orientation, the entire and unique bisecting line is their offset bisector. If the edges are parallel but have the same orientation, there is no offset bisector between them.

If the edges are collinear and have the same orientation, their offset bisector is given by a perpendicular ray to the left of the edges which originates at the midpoint of the combined complement of the edges. (The *complement* of an edge/segment are the two rays along its supporting line which are not the segment and the *combined*

Figure 16.4: Straight skeleton of a complex shaggy contour

Figure 16.5: Other examples: A vertex-event (left), the case of several collinear edges (middle), and the case of a validly simple polygon with tangent edges (right).

complement of N collinear segments is the intersection of the complements of each segment). If the edges are collinear but have opposite orientation, there is no offset bisector between them.

Faces, Edges and Vertices

Each region of the partitioning defined by a straight skeleton is called a *face*. Each face is bounded by straight line segments, called *edges*. Exactly one edge per face is a *contour edge* (corresponds to a side of the polygon) and the rest of the edges, located in the interior of the polygon, are called *skeleton edges*, or *bisectors*.

The bisectors of the straight skeleton are segments of the offset bisectors as defined previously. Since an offset bisector is a ray of a bisecting line of 2 contour edges, each skeleton edge (or bisector) is uniquely given by two contour edges. These edges are called the *defining contour edges* of the bisector.

The intersection of the edges are called *vertices*. Although in a simple polygon, only 2 edges intersect at a vertex, in a straight skeleton, 3 or more edges intersect at any given vertex. That is, vertices in a straight skeleton have degree ≥ 3 .

A *contour vertex* is a vertex for which 2 of its incident edges are contour edges.

A *skeleton vertex* is a vertex whose incident edges are all skeleton edges.

A *contour bisector* is a bisector whose defining contour edges are consecutive. Such a bisector is incident upon 1 contour vertex and 1 skeleton vertex and touches the input polygon at exactly 1 endpoint.

An *inner bisector* is a bisector whose defining contour edges are not consecutive. Such a bisector is incident upon 2 skeleton vertices and is strictly contained in the interior of the polygon.

16.2 Representation

This CGAL package represents a straight skeleton as a specialized *Halfedge Data Structure* (HDS) whose vertices embeds 2D Points (see the *StraightSkeleton_2* concept in the reference manual for details).

Its halfedges, by considering the source and target points, implicitly embeds 2D oriented straight line segments (each halfedge per se does not embed a segment explicitly).

A face of the straight skeleton is represented as a face in the HDS. Both contour and skeleton edges are represented by pairs of opposite HDS halfedges, and both contour and skeleton vertices are represented by HDS vertices.

In a HDS, a border halfedge is a halfedge which is incident upon an unbounded face. In the case of the straight skeleton HDS, such border halfedges are oriented such that their left side faces outwards the polygon. Therefore, the opposite halfedge of any border halfedge is oriented such that its left side faces inward the polygon.

This CGAL package requires the input polygon (with holes) to be non-degenerate, strictly-simple, and oriented counter-clockwise.

The skeleton halfedges are oriented such that their *left* side faces inward the region they bound. That is, the vertices (both contour and skeleton) of a face are circulated in counter-clockwise order. There is one and only one contour halfedge incident upon any face.

The contours of the input polygon are traced by the border halfedges of the HDS (those facing outward), but in the opposite direction. That is, the vertices of the contours can only be traced from the straight skeleton data

structure by circulating the border halfedges, and the resulting vertex sequence will be reversed w.r.t the input vertex sequence.

A skeleton edge, according to the definition given in the previous section, is defined by 2 contour edges. In the representation, each one of the opposite halfedges that represent a skeleton edge is associated with one of the opposite halfedges that correspond to one of its defining contour edges. Thus, the 2 opposite halfedges of a skeleton edge link the edge to its 2 defining contour edges.

Starting from any border contour halfedge, circulating the structure walks through border counter halfedges and traces the vertices of the polygon's contours (in opposite order).

Starting from any non-border but contour halfedge, circulating the structure walks counter-clockwise around the face corresponding to that contour halfedge. The vertices around a face always describe a non-convex non-degenerate strictly-simple polygon.

A vertex is the intersection of contour and/or skeleton edges. Since a skeleton edge is defined by 2 contour edges, any vertex is itself defined by a unique set of contour edges. These are called the *defining contour edges* of the vertex.

A vertex is identified by its set of defining contour edges. Two vertices are distinct if they have differing sets of defining contour edges. Note that vertices can be distinct even if they are geometrically embedded at the same point.

The *degree* of a vertex is the number of halfedges around the vertex incident upon (pointing to) the vertex. As with any halfedge data structure, there is one outgoing halfedge for each incoming (incident) halfedge around a vertex. The degree of the vertex counts only incoming (incident) halfedges.

In a straight skeleton, the degree of a vertex is not only the number of incident halfedges around the vertex but also the number of defining contour halfedges. The vertex itself is the point where all the defining contour edges simultaneously collide.

Contour vertices have exactly two defining contour halfedges, which are the contour edges incident upon the vertex; and 3 incident halfedges. One and only one of the incident halfedges is a skeleton halfedge. The degree of a contour vertex is exactly 3.

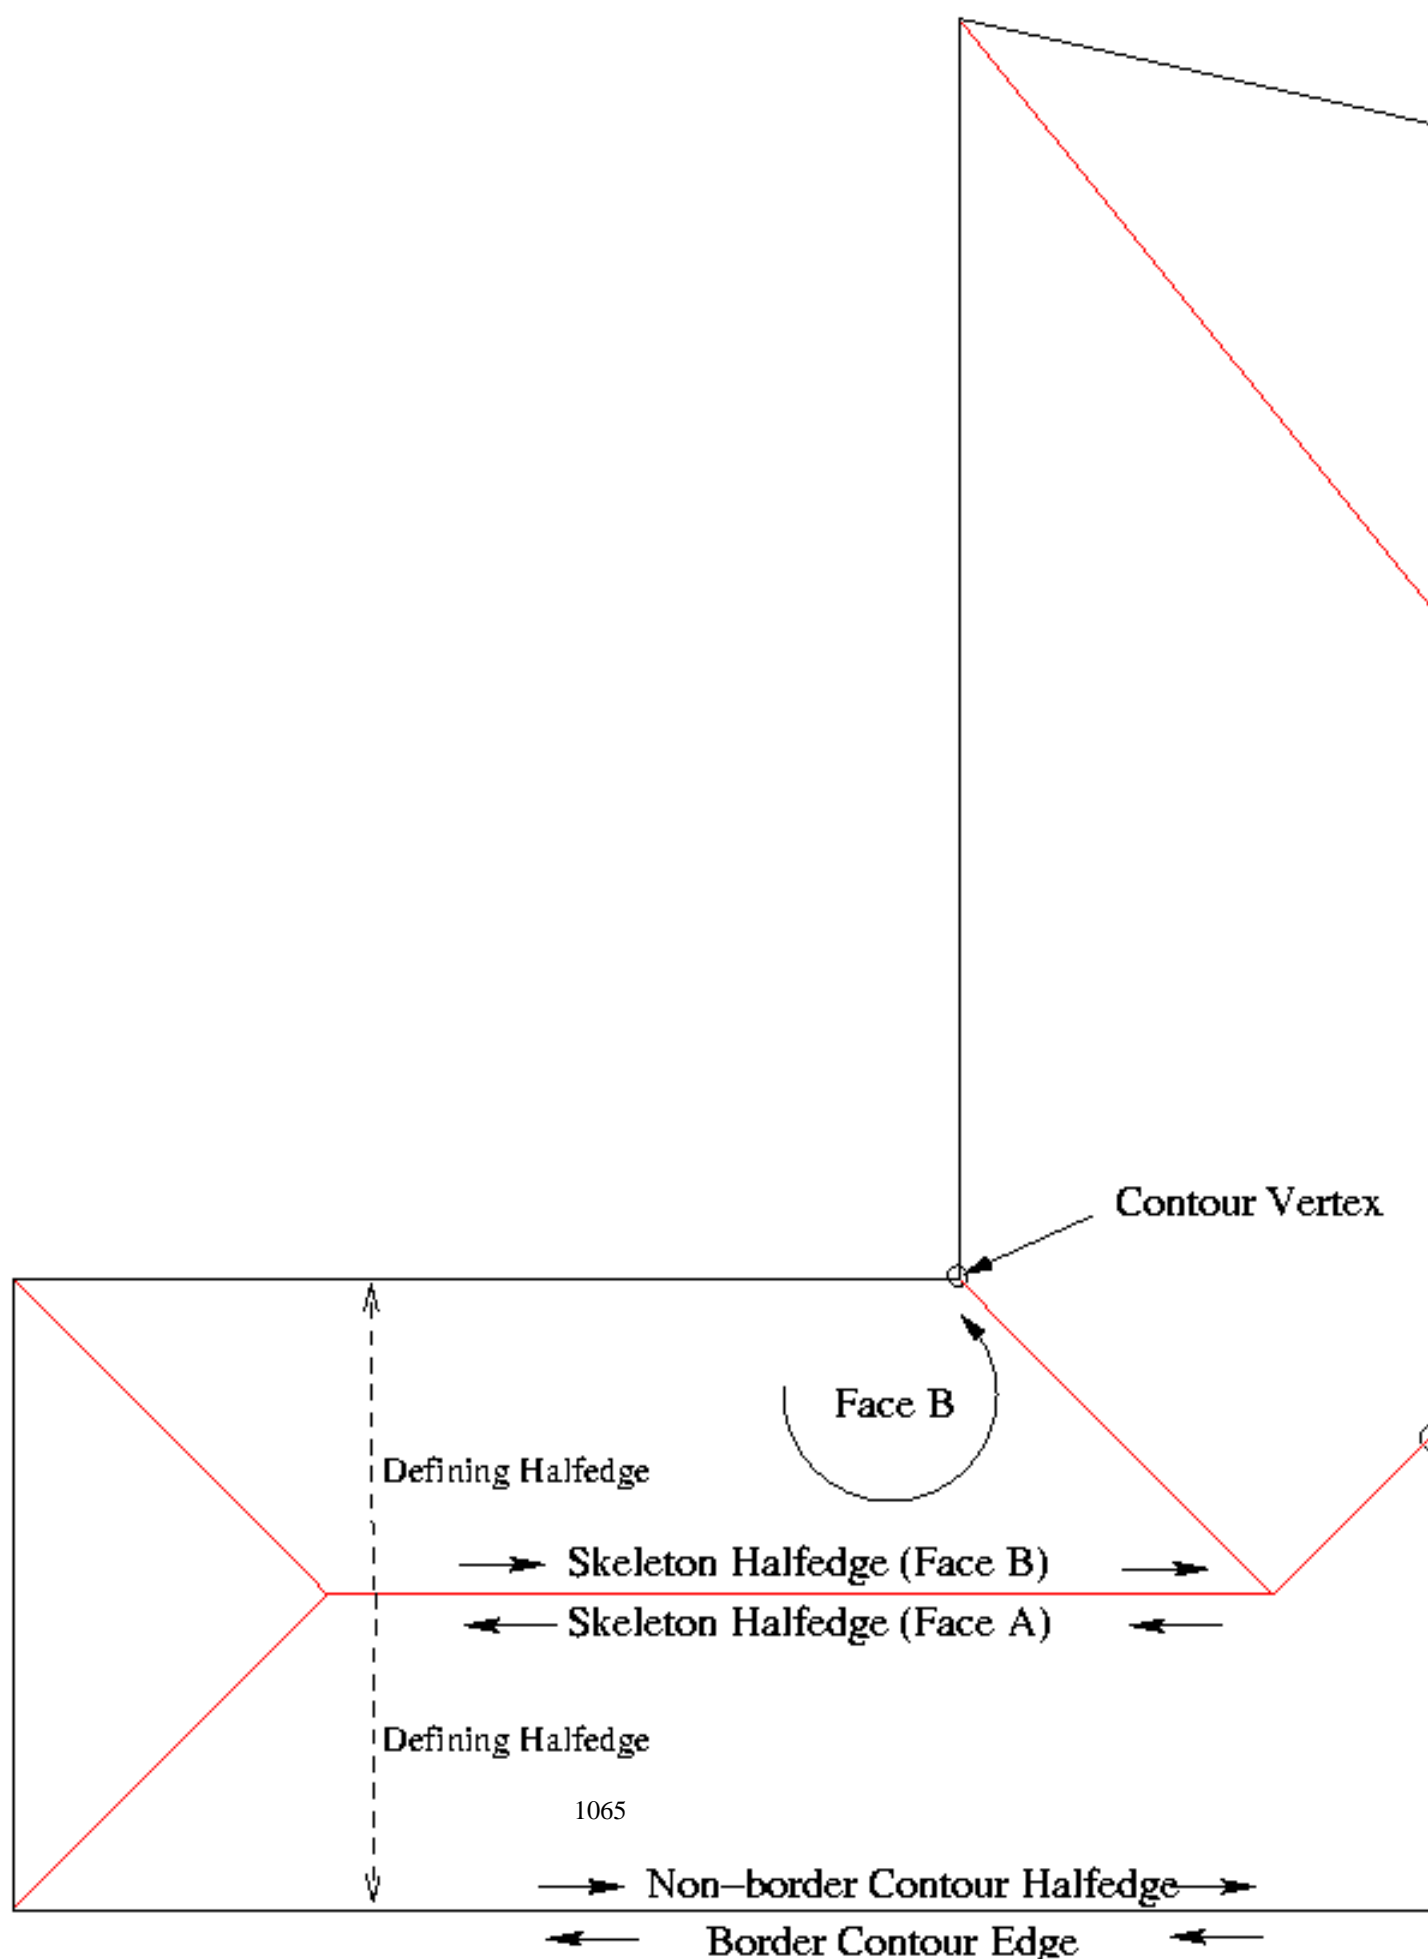

Skeleton vertices have at least 3 defining contour halfedges and 3 incident skeleton halfedges. If more than 3 edges collide simultaneously at the same point and time (like in any regular polygon with more than 3 sides), the corresponding skeleton vertex will have more than 3 defining contour halfedges and incident skeleton halfedges. That is, the degree of a skeleton vertex is ≥ 3 (the algorithm initially produces nodes of degree 3 but in the end all coincident nodes are merged to form higher degree nodes). All halfedges incident upon a skeleton vertex are skeleton halfedges.

The defining contour halfedges and incident halfedges around a vertex can be traced using the circulators provided by the vertex class. The degree of a vertex is not cached and cannot be directly obtained from the vertex, but you can calculate this number by manually counting the number of incident halfedges around the vertex.

Each vertex stores a 2D point and a *time*, which is the euclidean distance from the vertex's point to the *lines* supporting each of the defining contour edges of the vertex (the distance is the same to each line). Unless the polygon is convex, this distance is not equidistant to the edges, as in the case of a Medial Axis, therefore, the time of a skeleton vertex does not correspond to the distance from the polygon to the vertex (so it cannot be used to obtain the deep of a region in a shape, for instance).

If the polygon is convex, the straight skeleton is exactly equivalent to the polygon's voronoi diagram and each vertex time is the equidistance to the defining edges.

Contour vertices have time zero.

16.3 API

The straight skeleton data structure is defined by the *StraightSkeleton_2* concept and modeled in the *Straight_skeleton_2*<*Traits,Items,Alloc*> class.

The straight skeleton construction algorithm is encapsulated in the class *Straight_skeleton_builder_2*<*Gt,Ss*> which is parameterized on a geometric traits (class *Straight_skeleton_builder_traits*<*Kernel*>) and the Straight Skeleton class (*Ss*).

The offset contours construction algorithm is encapsulated in the class *Polygon_offset_builder_2*<*Ss,Gt,Container*> which is parameterized on the Straight Skeleton class (*Ss*), a geometric traits (class *Polygon_offset_builder_traits*<*Kernel*>) and a container type where the resulting offset polygons are generated.

To construct the straight skeleton of a polygon with holes the user must:

- (1) Instantiate the straight skeleton builder.
- (2) Enter one contour at a time, starting from the outer contour, via the method *enter_contour*. The input polygon with holes must be non-degenerate, strictly-simple and counter-clockwise oriented (see the definitions at the beginning of this chapter). Collinear edges are allowed. The insertion order of each hole is unimportant but the outer contour must be entered first.
- (3) Call *construct_skeleton* once *all* the contours have been entered. You cannot enter another contour once the skeleton has been constructed.

To construct a set of inward offset contours the user must:

- (1) Construct the straight skeleton of the source polygon with holes.
- (2) Instantiate the polygon offset builder passing in the straight skeleton as a parameter.
- (3) Call *construct_offset_contours* passing the desired offset distance and an output iterator that can store a *boost::shared_ptr* of *Container* instances into a resulting sequence (typically, a back insertion iterator)

Each element in the resulting sequence is an *offset contour*, given by a *boost::shared_ptr* holding a dynamically allocated instance of the *Container* type. Such a container can be any model of the *VertexContainer_2* concept, for example, a *CGAL::Polygon_2*, or just a *std::vector* of 2D points.

The resulting sequence of offset contours can contain both outer and inner contours. Each offset hole (inner offset contour) would logically belong in the interior of some of the outer offset contours. However, this algorithm returns a sequence of contours in arbitrary order and there is no indication whatsoever of the parental relationship between inner and outer contours.

On the other hand, each outer contour is counter-clockwise oriented while each hole is clockwise-oriented. And since offset contours do form simple polygons with holes, it is guaranteed that no hole will be inside another hole, no outer contour will be inside any other contour, and each hole will be inside exactly 1 outer contour.

Parental relationships are *not* automatically reconstructed by this algorithm because this relation is not directly given by the input polygon with holes and doing it *robustly* is a time-consuming operation.

A user can reconstruct the parental relationships as a post processing operation by testing each inner contour (which is identified by being clockwise) against each outer contour (identified as being counter-clockwise) for insideness.

This algorithm requires exact predicates but not exact constructions Therefore, the *Exact_predicates_inexact_constructions_kernel* should be used.

16.3.1 Exterior Skeletons and Exterior Offset contours

This CGAL package can only construct the straight skeleton and offset contours in the *interior* of a polygon with holes. However, constructing exterior skeletons and exterior offsets is possible:

Say you have some polygon made of 1 outer contour C0 and 1 hole C1, and you need to obtain some exterior offset contours.

The interior region of a polygon with holes is connected while the exterior region is not: there is an unbounded region outside the outer contour, and one bounded region inside each hole. To construct an offset contour you need to construct a straight skeleton. Thus, to construct exterior offset contours for a polygon with holes, you need to construct, *separately*, the exterior skeleton of the outer contour and the interior skeleton of each hole.

Constructing the interior skeleton of a hole is directly supported by this CGAL package; you just need to input the hole's vertices in reversed order as if it were an outer contour.

Constructing the exterior skeleton of the outer contour is possible by means of the following trick: place the contour as a hole of a big rectangle (call it *frame*). If the frame is sufficiently separated from the contour, the resulting skeleton will be practically equivalent to a *real* exterior skeleton.

To construct exterior offset contours in the inside of each hole you just use the skeleton constructed in the interior, and, if required, revert the orientation of each resulting offset contour.

Constructing exterior offset contours in the outside of the outer contour is just a little bit more involved: Since the contour is placed as a hole of a frame, you will always obtain 2 offset contours for any given distance; one is the offsetted frame and the other is the offsetted contour. Thus, from the resulting offset contour sequence, you always need to discard the offsetted frame, easily identified as the offset contour with the largest area.

It is necessary to place the frame sufficiently away from the contour. If it is not, it could occur that the outward offset contour collides and merges with the inward offset frame, resulting in 1 instead of 2 offset contours.

However, the proper separation between the contour and the frame is not directly given by the offset distance at which you want the offset contour. That distance must be at least the desired offset plus the largest euclidean distance between an offset vertex and its original.

This CGAL packages provides a helper function to compute the required separation: `compute_outer_frame_margin`

If you use this function to place the outer frame you are guaranteed to obtain an offset contour corresponding exclusively to the frame, which you can always identify as the one with the largest area and which you can simple remove from the result (to keep just the relevant outer contours).

16.3.2 Example

```
#include<vector>
#include<iterator>
#include<iostream>
#include<iomanip>
#include<string>

#include<boost/shared_ptr.hpp>

#include<CGAL/basic.h>
#include<CGAL/Cartesian.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Straight_skeleton_builder_2.h>
#include<CGAL/Polygon_offset_builder_2.h>
#include<CGAL/compute_outer_frame_margin.h>

//
```

```

// This example illustrates how to use the CGAL Straight Skeleton package
// to construct an offset contour on the outside of a polygon
//

// This is the recommended kernel
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;

typedef Kernel::Point_2 Point_2;
typedef CGAL::Polygon_2<Kernel> Contour;
typedef boost::shared_ptr<Contour> ContourPtr;
typedef std::vector<ContourPtr> ContourSequence ;

typedef CGAL::Straight_skeleton_2<Kernel> Ss;

typedef Ss::Halfedge_iterator Halfedge_iterator;
typedef Ss::Halfedge_handle Halfedge_handle;
typedef Ss::Vertex_handle Vertex_handle;

16.4 Straight Skeletons, Medial Axis and Voronoi Diagrams

The straight skeleton of a polygon is similar to the medial axis and the voronoi diagram of a polygon in the way it partitions it; however, unlike the medial axis and voronoi diagram, the bisectors are not equidistant to its defining edges but to the supporting lines of such edges. As a result, Straight Skeleton bisectors might not be located in the center of the polygon and so cannot be regarded as a proper Medial Axis in its geometrical meaning.

On the other hand, only reflex vertices (whose internal angle $> \pi$) are the source of deviations of the bisectors from its center location. Therefore, for convex polygons, the straight skeleton, the medial axis and the Voronoi diagram are exactly equivalent, and, if a non-convex polygon contains only vertices of low reflexivity, the straight skeleton bisectors will be placed nearly equidistant to their defining edges, producing a straight skeleton pretty much alike a proper medial axis.

16.5 Usages of the Straight Skeletons

The most natural usage of straight skeletons is offsetting: growing and shrinking polygons (provided by this CGAL package).

Another usage, perhaps its very first, is roof design: The straight skeleton of a polygonal roof directly gives the layout of each tent. If each skeleton edge is lifted from the plane a height equal to its offset distance, the resulting roof is "correct" in that water will always fall down to the contour edges (roof border) regardless of where in the roof it falls. [LD03] gives an algorithm for roof design based on the straight skeleton.

Just like medial axes, 2D straight skeletons can also be used for 2D shape description and matching. Essentially, all the applications of image-based skeletonization (for which there is a vast literature) are also direct applications of the straight skeleton, specially since skeleton edges are simply straight line segments.

Consider the subgraph formed only by *inner bisectors* (that is, only the skeleton halfedges which are not incident upon a contour vertex). Call this subgraph a *skeleton axis*. Each node in the skeleton axis whose degree is ≥ 3 roots more than one skeleton tree. Each skeleton tree roughly corresponds to a region in the input topologically equivalent to a rectangle; that is, without branches. For example, a simple letter "H" would contain 2 higher degree nodes separating the skeleton axis in 5 trees; while the letter "@" would contain just 1 higher degree node separating the skeleton axis in 2 curly trees.

Since a skeleton edge is a 2D straight line, each branch in a skeleton tree is a polyline. Thus, the path-length of the tree can be directly computed. Furthermore, the polyline for a particular tree can be interpolated to obtain curve-related information.

Pruning each skeleton tree cutting off branches whose length is below some threshold; or smoothing a given branch, can be used to reconstruct the polygon without undesired details, or fit into a particular canonical shape.

Each skeleton edge in a skeleton branch is associated with 2 contour edges which are facing each other. If the polygon has a bottleneck (it almost touches itself), a search in the skeleton graph measuring the distance between each pair of contour edges will reveal the location of the bottleneck, allowing you to cut the shape in two. Likewise, if two shapes are too close to each other along some part of their boundaries (a near contact zone), a similar search in an exterior skeleton of the two shapes at once would reveal the parts of near contact, allowing you to stitch the shapes. These *cut and stitch* operations can be directly executed in the straight skeleton itself instead of the input polygon (because the straight skeleton contains a graph of the connected contour edges).

16.6 Straight Skeleton of a General Figure in the Plane

A straight skeleton can also be defined for a general multiply-connected planar directed straight-line graph [AA95] by considering all the edges as embedded in an unbounded region. The only difference is that in this case some faces will be only partially bounded.

The current version of this CGAL package can only construct the straight skeleton in the interior of a simple polygon with holes, that is it doesn't handle general polygonal figures in the plane.

2D Straight Skeleton and Polygon Offsetting

Reference Manual

This chapter introduces the concepts and classes that correspond to the CGAL *2D Straight Skeleton* package. The packages provides an algorithm for the construction of the straight skeleton in the interior of a simple polygon with holes and an algorithm for the construction of inward offset contours based on the straight skeleton.

StraightSkeleton_2

Definition

The concept `StraightSkeleton_2` describes the requirements for the data structure used to represent a straight skeleton.

Refines

HalfedgeDS

Types

StraightSkeleton_2::Vertex

A model of the *StraightSkeletonVertex_2* concept used to represent the vertices of the straight skeleton

StraightSkeleton_2::Halfedge

A model of the *StraightSkeletonHalfedge_2* concept used to represent the halfedges of the straight skeleton

StraightSkeleton_2::Face

Any model of the *HalfedgeDSFace* concept

Has Models

CGAL::Straight_skeleton_2<Traits,Items,Alloc>.

This concept explicitly protects all the modifying operations of the base *HalfedgeDS* concept. Only the algorithm classes, or clients explicitly bypassing the protection mechanism, can modify a straight skeleton.

StraightSkeletonVertex_2

Definition

The concept `StraightSkeletonVertex_2` describes the requirements for the vertex type of the *StraightSkeleton_2* concept. It is a refinement of the *HalfedgeDSVertex* concept with support for storage of the incident halfedge. The `StraightSkeletonVertex_2` concept requires the geometric embedding to be a 2D point.

Refines

HalfedgeDSVertex

Types

<i>StraightSkeletonVertex_2:: Point_2</i>	The type of the 2D point being the geometric embedding of the vertex
<i>StraightSkeletonVertex_2:: FT</i>	A model of the <i>SqrtFieldNumberType</i> concept representing the time of a vertex (an Euclidean distance)
<i>StraightSkeletonVertex_2:: Halfedge_around_vertex_const_circulator</i> <i>StraightSkeletonVertex_2:: Halfedge_around_vertex_circulator</i>	The circulator type used to visit all the incident halfedges around a vertex
<i>StraightSkeletonVertex_2:: Defining_contour_halfedge_const_circulator</i> <i>StraightSkeletonVertex_2:: Defining_contour_halfedge_circulator</i>	The circulator type used to visit all the defining contour halfedges of a vertex

Creation

<i>StraightSkeletonVertex_2</i> <i>v</i> ;	Default constructor
<i>StraightSkeletonVertex_2</i> <i>v</i> (<i>int id</i> , <i>Point_2 p</i>);	Constructs a contour vertex with ID number <i>id</i> , at the point <i>p</i>
<i>StraightSkeletonVertex_2</i> <i>v</i> (<i>int id</i> , <i>Point_2 p</i> , <i>FT time</i>);	Constructs a skeleton vertex with ID number <i>id</i> , at point <i>p</i> and time <i>time</i> .

Access Functions

<i>int</i>	<i>v.id()</i>	The ID of the vertex.
<i>Point_2</i>	<i>v.point()</i>	The vertex point.
<i>FT</i>	<i>v.time()</i>	The time of the vertex: the distance from the vertex point to the lines supporting the defining contour edges
<i>Halfedge_handle</i>	<i>v.primary_bisector()</i>	

Halfedge_const_handle

v.primary_bisector() Returns the skeleton halfedge incident upon the vertex (called the *primary* bisector).

Halfedge_around_vertex_circulator

v.halfedge_around_vertex_begin()

Halfedge_around_vertex_const_circulator

v.halfedge_around_vertex_begin()

Returns a bi-directional circulator pointing to one of the incident halfedges (which one is unspecified).

There will always be as many incident halfedges as the degree of the vertex.

If this is a *contour* vertex, its degree is exactly 3, and from the halfedges pointed to by the circulator, 2 are contour and 1 is a bisector.

If this is an *skeleton* vertex, its degree is at least 3 and all of the halfedges pointed to by the circulator are bisectors.

Each halfedge pointed to by this circulator is the one which is oriented towards the vertex (according to the geometric embedding).

Defining_contour_halfedge_circulator

v.defining_contour_halfedges_begin()

Defining_contour_halfedge_const_circulator

v.defining_contour_halfedges_begin()

Returns a bi-directional circulator pointing to one of the defining contour halfedges of the vertex (which one is unspecified).

There will always be as many incident defining contour halfedges as the degree of the vertex.

Each halfedge pointed to by this circulator is the one having its left side facing inwards (which happens to be the contour halfedge for which *is_border()* is *false*).

Queries

<i>bool</i>	<i>v.is_contour()</i>	Returns <i>true</i> iff this is a contour vertex.
<i>bool</i>	<i>v.is_skeleton()</i>	Returns <i>true</i> iff this is a skeleton vertex.

StraightSkeletonHalfedge_2

Definition

The concept `StraightSkeletonHalfedge_2` describes the requirements for the halfedge type of the `StraightSkeleton_2` concept. It is a refinement of the `HalfedgeDSHalfedge` concept. The `StraightSkeletonHalfedge_2` concept requires no geometric embedding at all. The only geometric embedding used by the Straight Skeleton Data Structure are the 2D points in the contour and skeleton vertices. However, for any halfedge, there is a 2D segment implicitly given by its *source* and *target* vertices.

Refines

`HalfedgeDSHalfedge`

Creation

<code>StraightSkeletonHalfedge_2 h;</code>	Default Constructor.
<code>StraightSkeletonHalfedge_2 h(int id);</code>	Constructs a halfedge with ID <i>id</i> . It is the links to other halfedges what determines if this is a contour edge, a contour-skeleton edge or an inner-skeleton edge.

Access Functions

<code>Halfedge_handle</code>	<code>h.defining_contour_edge()</code>	
<code>Halfedge_const_handle</code>	<code>h.defining_contour_edge()</code>	If this is a bisector halfedge, returns a handle to the inward-facing (non-border) contour halfedge corresponding to the defining contour edge which is to its left; if this is a contour halfedge, returns a handle to itself if <i>is_border()</i> is <i>false</i> , or to its opposite if it is <i>true</i> .

Queries

<code>bool</code>	<code>h.is_bisector()</code>	Returns <i>true</i> iff this is a bisector (or skeleton) halfedge (i.e. is not a contour halfedge).
<code>bool</code>	<code>h.is_inner_bisector()</code>	Returns <i>true</i> iff this is a bisector and is inner (i.e. is not incident upon a contour vertex).

StraightSkeletonBuilderTraits_2

Definition

The concept `StraightSkeletonBuilderTraits_2` describes the requirements for the geometric traits class required by the algorithm class `Straight_skeleton_builder_2<Gt, Ss>`.

Types

<code>StraightSkeletonBuilderTraits_2:: Kernel</code>	A model of the <i>Kernel</i> concept.
<code>StraightSkeletonBuilderTraits_2:: FT</code>	A <i>SqrtFieldNumberType</i> provided by the kernel. This type is used to represent the coordinates of the input points, of the skeleton nodes and as the event time stored in the skeleton nodes.
<code>boost::tuple<FT, FT> Vertex;</code>	A pair of (x,y) coordinates representing a 2D cartesian point.
<code>boost::tuple<Vertex, Vertex></code>	
<code>Edge;</code>	A pair of vertices representing an edge
<code>boost::tuple<Edge, Edge, Edge></code>	
<code>EdgeTriple;</code>	A triple of edges representing an event
<code>StraightSkeletonBuilderTraits_2:: Equal_2</code>	
	A predicate object type being a model of the <i>Kernel::Equal_2</i> function object concept.
<code>StraightSkeletonBuilderTraits_2:: Left_turn_2</code>	
	A predicate object type being a model of the <i>Kernel::LeftTurn_2</i> function object concept.
<code>StraightSkeletonBuilderTraits_2:: Collinear_2</code>	
	A predicate object type being a model of the <i>Kernel::Collinear_2</i> function object concept.
<code>StraightSkeletonBuilderTraits_2:: Do_ss_event_exist_2</code>	
	A predicate object type. Must provide <i>bool operator()(EdgeTriple const& et) const</i> , which determines if, given the 3 <i>oriented</i> lines defined by the 3 input edges (3 pair of points), there exist an Euclidean distance $t \geq 0$ for which the corresponding 3 <i>offset lines at t</i> (parallel lines at an Euclidean distance of t) intersect in a single point. <i>Precondition:</i> each edge in the triple must properly define an oriented line, that is, such points cannot be coincident.

StraightSkeletonBuilderTraits_2:: Compare_ss_event_times_2

A predicate object type.

Must provide *Comparison_result operator()(EdgeTriple const& x, EdgeTriple const& y) const*, which compares the *times* for the events determined by the edge-triples *x* and *y*.

The time of an event given by an edge triple (which defines 3 oriented lines) is the Euclidean distance *t* at which the corresponding offset lines at *t* intersect in a single point.

Precondition: *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Compare_ss_event_distance_to_seed_2

A predicate object type.

Must provide *Comparison_result operator()(Point_2 const& p, EdgeTriple const& x, EdgeTriple const& y)*, which compares the Euclidean distance of the points of event for *x* and *y* to the point *p*.

The point of an event given by an edge triple (which defines 3 oriented lines) is the intersection point of the 3 corresponding offset lines at the time *t* of the event.

It must also provide *Comparison_result operator(EdgeTriple const& seed, EdgeTriple const& x, EdgeTriple const& y)()* which makes the same comparison as the first overload but where the seed point is given implicitly as the point of event for *seed*.

Precondition: *seed*, *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Is_ss_event_inside_offset_zone_2

A predicate object type.

Must provide *bool operator()(EdgeTriple const& e, EdgeTriple const& zone)*, which determines if the point of event for *e* is inside the *offset zone* defined by the 3 *oriented* lines given by *zone*.

An offset zone given by 3 *oriented* lines is the intersection of the halfplanes to the left of each oriented line.

Precondition: *e* must be an edge-triple corresponding to an event that actually exist (as determined by the predicate *Exist_sls_event_2*), and the 3 oriented lines given by *zone* must be well defined (no point-pair can have coincident points).

StraightSkeletonBuilderTraits_2:: Are_ss_events_simultaneous_2

A predicate object type.

Must provide *bool operator()(EdgeTriple const& x, EdgeTriple const& y)*, which determines if the events given by *x* and *y* are coincident in time and space; that is, both triples of offset lines intersect at the same point and at the same Euclidean distance from their sources.

Precondition: *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Construct_ss_event_time_and_point_2

A construction object type.

Must provide *boost::tuple< boost::optional<FT>, boost::optional<Point_2> > operator()(EdgeTriple const& e)*, which given the 3 *oriented* lines defined by the 3 input edges (3 pair of points), returns the Euclidean distance $t \geq 0$ and intersection point at which the corresponding 3 *offset lines* at t intersect.

If the values cannot be computed, not even approximately (because of overflow for instance), an empty optional must be returned.

Precondition: e must be an edge-triple corresponding to an event that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Construct_ss_vertex_2

A construction object type.

Must provide *Vertex operator()(Point_2 const& p)*, which given a *Point_2* p returns a Vertex encapsulating the corresponding (x,y) pair of *cartesian* coordinates.

StraightSkeletonBuilderTraits_2:: Construct_ss_edge_2

A construction object type.

Must provide *Edge operator()(Point_2 const& s, Point_2 const& t)*, which given source and target points s and t returns an Edge encapsulating the corresponding input segment (in *cartesian* coordinates.)

StraightSkeletonBuilderTraits_2:: Construct_ss_triedge_2

A construction object type.

Must provide *Triedge operator()(Edge const& e0, Edge const& e1, Edge const& e2)*, which given the 3 edges that define an event, $e0$, $e1$ and $e2$, returns a Triedge encapsulating them.

PolygonOffsetBuilderTraits_2

Definition

The concept `PolygonOffsetBuilderTraits_2` describes the requirements for the geometric traits class required by the algorithm class `Polygon_offset_builder_2<Ss,Gt,Polygon_2>`.

Types

<code>PolygonOffsetBuilderTraits_2:: Kernel</code>	A model of the <i>Kernel</i> concept.
<code>PolygonOffsetBuilderTraits_2:: FT</code>	A <i>SqrtFieldNumberType</i> provided by the kernel. This type is used to represent the coordinates of the input points and to specify the desired offset distance.
<code>PolygonOffsetBuilderTraits_2:: Point_2</code>	A 2D point type
<code>boost::tuple<FT,FT> Vertex;</code>	A pair of (x,y) coordinates representing a 2D Cartesian point.
<code>boost::tuple<Vertex,Vertex></code>	
<code>Edge;</code>	A pair of vertices representing an edge
<code>boost::tuple<Edge,Edge,Edge></code>	
<code>EdgeTriple;</code>	A triple of edges representing an event

`PolygonOffsetBuilderTraits_2:: Compare_offset_against_event_time_2`

A predicate object type.
 Must provide `Comparison_result operator()(FT d, EdgeTriple const& et) const`, which compares the Euclidean distance d with the event time for et . Such event time is the Euclidean distance at which the *offset lines* intersect in a single point. The source of such offset lines is given by the 3 *oriented* lines defined by the edge-triple et
Precondition: et must be an edge-triple corresponding to an event that actually exist (that is, there must exist an offset distance $t > 0$ at which the offset lines do intersect at a single point.

`PolygonOffsetBuilderTraits_2:: Construct_offset_point_2`

A construction object type.
 Must provide `boost::optional<Point_2> operator()(FT t, Edge const& x, Edge const& y) const`, which constructs the point of intersection of the lines obtained by offsetting the oriented lines given by x and y an Euclidean distance t . If the point cannot be computed, not even approximately (because of overflow for instance), an empty optional must be returned.

Precondition: x and y must intersect in a single point

`PolygonOffsetBuilderTraits_2:: Construct_ss_vertex_2`

A construction object type.
 Must provide `Vertex operator()(Point_2 const& p)`, which given a *Point_2* p returns a *Vertex* encapsulating the corresponding (x,y) pair of Cartesian coordinates.

PolygonOffsetBuilderTraits_2:: Construct_ss_edge_2

A construction object type.

Must provide *Edge operator()*(*Point_2 const& s*, *Point_2 const& t*), which given source and target points *s* and *t* returns an *Edge* encapsulating the corresponding input segment (in Cartesian coordinates.)

PolygonOffsetBuilderTraits_2:: Construct_ss_triedge_2

A construction object type.

Must provide *Triedge operator()*(*Edge const& e0*, *Edge const& e1*, *Edge const& e2*), which given the 3 edges that define an event, *e0*, *e1* and *e2*, returns a *Triedge* encapsulating them.

VertexContainer_2

Introduction

A model for the `VertexContainer_2` concept defines the requirements for a resizable container of 2D points. It is used to output the offset polygons generated by the `Polygon_offset_builder_2<Ssds,Gt,Container>` class.

Types

<code>VertexContainer_2:: Point_2</code>	A 2D point type used to represent a vertex. Must be a model of the <code>Kernel::Point_2</code> concept
<code>VertexContainer_2:: size_type</code>	A unsigned integral type that can represent the number of vertices in the container.

Creation

<code>VertexContainer_2 c;</code>	Default constructor
<code>size_type</code> <code>c.size()</code>	Returns the number of vertices in the container.
<code>void</code> <code>c.push_back(Point_2 v)</code>	Adds the vertex <code>v</code> to the container, resizing its capacity if required.

Has Models

`CGAL::Polygon_2`

Any standard `BackInsertionSequence`, such as `vector`, `list` or `deque`, with a `value_type` being a model of the `Kernel::Point_2` concept.

CGAL::Straight_skeleton_2<Traits,Items,Alloc>

Definition

The class *Straight_skeleton_2*<Traits,Items,Alloc> provides a model for the *StraightSkeleton_2* concept which is the class type used to represent a straight skeleton.

It inherits from *HalfedgeDS_vector*<Traits,Items,Alloc>

```
#include <CGAL/Straight_skeleton_2.h>
```

Is Model for the Concepts

StraightSkeleton_2
DefaultConstructible
CopyConstructible
Assignable

See Also

StraightSkeletonVertex_2
StraightSkeletonHalfedge_2
StraightSkeleton_2

The only purpose of this class is to protect all the modifying operations in a *HalfedgeDS*. Normal users should not modify a straight skeleton. If an advanced user needs to get access to the modifying operations, it must call the required methods through the *::Base* class.

CGAL::Straight_skeleton_vertex_base_2<Refs,Point,FT>

Definition

The class *Straight_skeleton_vertex_base_2<Refs,Point,FT>* provides a model for the *StraightSkeletonVertex_2* concept which is the vertex type required by the *StraightSkeleton_2* concept. The class *Straight_skeleton_vertex_base_2<Refs,Point,FT>* has three template arguments: the first is the model of the *StraightSkeleton_2* concept (the vertex container), the second is a Point type, and the third is a model of the *SqrtFieldNumberType*, which is the numeric type used to represent the time of a vertex (a Euclidean distance).

This class can be used as a base class allowing users of the straight skeleton data structure to decorate a vertex with additional data. The concrete vertex class must be given in the *HalfedgeDSItems* template parameter of the instantiation of the *HalfedgeDS_default* class used as the model for the *Straight_skeleton_2* concept.

```
#include <CGAL/Straight_skeleton_vertex_base_2.h>
```

CGAL::Straight_skeleton_builder_traits_2<Kernel>

Definition

The class *Straight_skeleton_builder_traits_2<Kernel>* provides a model for the *StraightSkeletonBuilderTraits_2* concept which is the traits class required by the *Straight_skeleton_builder_2* algorithm class. The class *Straight_skeleton_builder_traits_2<Kernel>* has one template argument: a 2D CGAL Kernel. This parameter must be a model for the *Kernel* concept, such as the *Exact_predicates_inexact_constructions_kernel*, which is the recommended one.

It is unspecified which subset of the kernel is used into the output sequence and the returned iterator will be equal to *out*.

For any given input polygon, it in this traits class (and by extension in the builder class). This is to avoid restricting the choices in the implementation.

```
#include <CGAL/Straight_skeleton_builder_traits_2.h>
```

CGAL::Straight_skeleton_builder_2<Gt,Sds>

CGAL::Straight_skeleton_builder_2<Gt,Ss>

Definition

The class *Straight_skeleton_builder_2*<Gt,Ss> encapsulates the construction of the 2D straight skeleton in the interior of a polygon with holes. Its first template parameter, *Gt*, must be a model of the *StraightSkeletonBuilderTraits_2* concept, and its second template parameter, *Ss*, must be a model of the *StraightSkeleton_2* concept.

```
#include <CGAL/Straight_skeleton_builder_2.h>
```

Types

<i>Straight_skeleton_builder_2</i> <Gt,Ss>:: <i>Gt</i>	The geometric traits (first template parameter)
<i>Straight_skeleton_builder_2</i> <Gt,Ss>:: <i>Ss</i>	The straight skeleton (second template parameter)
<i>Straight_skeleton_builder_2</i> <Gt,Ss>:: <i>Point_2</i>	The 2D point type as defined by the geometric traits

Creation

<i>Straight_skeleton_builder_2</i> <Gt,Ss> <i>b</i> ;	Default constructs the builder class.
-------------------------------------------------------	---------------------------------------

Methods

```
template<class InputPointIterator>
Straight_skeleton_builder_2&
```

```
    b.enter_contour( InputPointIterator aBegin, InputPointIterator aEnd)
```

Defines the *contours* that form the *non-degenerate strictly-simple polygon with holes* whose *straight skeleton* is to be built.

Each contour must be input in turn starting with the *outer contour* and following with the holes (if any). The order of the holes is unimportant but the outer contour must be entered first. The outer contour must be oriented counter-clockwise while holes must be oriented clockwise.

It is an error to enter more than one outer contour or to enter a hole which is not inside the outer contour or inside another hole. It is also an error to enter a contour which crosses or touches any one another. It is possible however to enter a contour that touches itself in such a way that its interior region is still well defined and singly-connected (see the User Manual for examples).

The sequence [aBegin,aEnd) must iterate over each 2D point that corresponds to a vertex of the contour being entered. Vertices cannot be coincident (except consecutively since the method simply skip consecutive coincident vertices). Consecutive collinear edges are allowed.

InputPointIterator must be an *InputIterator* whose *value_type* is *Point_2*.

`boost::shared_ptr<Ss>`

`b.construct_skeleton()`

Constructs and returns the 2D straight skeleton in the interior of the polygon with holes as defined by the contours entered first by calling `enter_contour`. All the contours of the polygon with holes must be entered before calling `construct_skeleton`.

After `construct_skeleton` completes, you cannot enter more contours and/or call `construct_skeleton()` again. If you need another straight skeleton for another polygon you must instantiate and use another builder.

The result is a dynamically allocated instance of the `Ss` class, wrapped in a `boost::shared_ptr`.

If the construction process fails for whatever reason (such as a nearly-degenerate vertex whose internal or external angle is almost zero), the return value will be `null`, represented by a default constructed `shared_ptr`.

The algorithm automatically checks the consistency of the result, thus, if it is not `null`, it is guaranteed to be valid.

Algorithm

The implemented algorithm is closely based on [FO98] with the addition of *vertex events* as described in [EE98].

It simulates a grassfire propagation of moving polygon edges as they move inward at constant and equal speed. That is, the continuous inward offsetting of the polygon.

Since edges move at equal speed their movement can be characterized in a simpler setup as the movement of vertices. Vertices move along the angular bisector of adjacent edges.

The trace of a moving vertex is described by the algorithm as a *bisector*. Every position along a bisector corresponds to the vertex between two offset (moved) edges. Since edges move at constant speed, every position along a bisector also corresponds to the distance those two edges moved so far.

From the perspective of a dynamic system of moving edges, such a distance can be regarded as an *instant* (in time). Therefore, every distinct position along a bisector corresponds to a distinct instant in the offsetting process.

As they move inward, edges can expand or contract w.r.t to the endpoints sharing a vertex. If a vertex has an internal angle $< \pi$, its incident edges will contract but if its internal angle $> \pi$, they will expand. The movement of the edges, along with their extent change, result in collisions between non-adjacent edges. These collisions are called *events*, and they occur when the colliding edges have moved a certain distance, that is, at certain *instants*.

If non-consecutive edges $E(j), E(k)$ move while edge $E(i)$ contracts, they can collide at the point when $E(i)$ shrinks to nothing (that is, the three edges might meet at a certain offset). This introduces a *topological change* in the polygon: Edges $E(j), E(k)$ are now adjacent, edge $E(i)$ disappears, and a new vertex appears. This topological change is called an *edge event*.

Similarly, consecutive expanding edges $E(i), E(i+1)$ sharing a reflex vertex (internal angle $\geq \pi$) might collide with any edge $E(j)$ on the rest of the same connected component of the polygon boundary (even far away from the initial edge's position). This also introduces a topological change: $E(j)$ gets split in two edges and the connected component having $E(i), E(i+1)$ and $E(j)$ is split in two unconnected parts: one having $E(i)$ and the corresponding subsegment of $E(j)$ and the other with $E(i+1)$ and the rest of $E(j)$. This is called a *split event*.

If a reflex vertex hits not an edge $E(j)$ but another reflex vertex $E(j), E(j+1)$, and viceversa (the reflex vertex $V(j)$ hits $V(i)$), there is no actual split and the two unconnected parts have $E(i), E(j)$ and $E(i+1), E(j+1)$ (or $E(i), E(j+1)$ and $E(i+1), E(j)$). This topological change is called a *vertex event*. Although similar to a split event in the sense

that two new unconnected contours emerge introducing two new contour vertices, in the case of a vertex event one of the new contour vertices might be reflex; that is, a vertex event *may* result in one of the offset polygons having a *reflex* contour vertex which was not in the original polygon.

Edges movement is described by vertices movement, and these by bisectors. Therefore, the collision between edges $E(j), E(i), E(k)$ (all in the same connected component) occurs when the moving vertices $E(j) \rightarrow E(i)$ and $E(i) \rightarrow E(k)$ meet ; that is, when the two bisectors describing the moving vertices *intersect* (Note: as the edges move inward and events occur, a vertex between edges A and B might exist even if A and B are not consecutive; that is, j and k are not necessarily i-1 and i+1 respectively, although initially they are).

Similarly, the collision between $E(i), E(i+1)$ with $E(j)$ (all in the same connected component) occurs when the bisector corresponding to the moving vertex $E(i) \rightarrow E(i+1)$ hits the moving edge $E(j)$.

Since each event changes the topology of the moving polygon, it is not possible or practical to foresee all events at once. Rather, the algorithm starts by estimating an initial set of potential events and from there it computes one next event at a time based on the previous one. The chaining of events is governed by their relative instants: events that occur first are processed first.

An initial set of *potential* split events is first computed independently (the computation of a potential split event is based solely on a reflex vertex and all other edges in the same connected component); and an initial set of *potential* edge events between initially consecutive bisectors is first computed independently (based solely on each bisector pair under consideration).

Events occur at certain instants and the algorithm must be able to order them accordingly. The correctness of the algorithm is uniquely and directly governed by the correct computation and ordering of the events. Any potential event might no longer be applicable after the topological change introduced by a prior event.

A grassfire propagation picks the next unprocessed event (starting from the first) and if it is still applicable processes it. Processing an event involves connecting edges, adding a new skeleton vertex (which corresponds to a contour vertex of the offset polygon) and calculating one new potential future event (which can be either an edge event or a split event -because of a prior vertex event-), based on the topological change just introduced. The propagation finishes when there are no new future events.

CGAL::Polygon_offset_builder_2<Ss,Gt,Polygon_2>

CGAL::Polygon_offset_builder_2<Ss,Gt,Container>

Definition

The class *Polygon_offset_builder_2*<*Ss,Gt,Container*> encapsulates the construction of inward offset contours of a 2D simple polygon with holes. The construction is based on the straight skeleton of the interior of the polygon. Its first template parameter, *Ss*, must be a model of the *StraightSkeleton_2* concept, its second template parameter, *Gt*, must be a model of the *StraightSkeletonBuilderTraits_2* concept, and its third template parameter must be a model of the *VertexContainer_2* concept.

```
#include <CGAL/Polygon_offset_builder_2.h>
```

Types

Polygon_offset_builder_2<*Ss,Gt,Container*>:: *Ss*

The straight skeleton (first template parameter)

Polygon_offset_builder_2<*Ss,Gt,Container*>:: *Gt*

The geometric traits (second template parameter)

Polygon_offset_builder_2<*Ss,Gt,Container*>:: *Container*

The container of 2D vertices that represents each offset contour generated by the algorithm (third template parameter)

Polygon_offset_builder_2<*Ss,Gt,Container*>:: *FT*

The *SqrtFieldNumberType* used to specify the desired offset distance, provided by the geometric traits *Gt*.

Creation

Polygon_offset_builder_2<*Ss,Gt,Container*> *b*(*Ss ss*);

Constructs the builder class using the given Straight Skeleton instance.

Methods

```
template<class OutputIterator>
```

OutputIterator *b.construct_offset_contours(FT t, OutputIterator out)*

Given the straight skeleton passed in the constructor which corresponds to the interior of a non-degenerate strictly-simple polygon with holes *P*, returns *all* the offset contours of *P* at the Euclidean distance *t*.

Such offset contours are simple polygons in the interior of *P*.

For any offset distance *t* there are 0, 1 or more offset contours.

For each resulting offset contour, a default constructed instance of *Container* type (which must be a model of the *VertexContainer_2* concept), is dynamically allocated and each offset vertex is added to it.

A *boost::shared_ptr* holding onto the dynamically allocated container is inserted into the output sequence via the *OutputIterator out*.

OutputIterator must be a model of the *OutputIterator* category whose *value_type* is a *boost::shared_ptr* holding the dynamically allocated instances of type *Container*.

The method returns an *OutputIterator* past-the-end of the resulting sequence, which contains each offset contour generated.

You can call *construct_offset_contours* with different offset distances (there is no need to construct the builder again). If you call it with an offset distance so large that there are no offset contours at that distance, no contour is inserted into the output sequence and the returned iterator will be equal to *out*.

For any given input polygon, its offset polygons at a certain distance are composed of several contours. This method returns all such contours in an unspecified order and with no parental relationship between them (that is why it is called *construct_offset_contours* and not *construct_offset_polygons*).

Those offset contours in the resulting sequence which are oriented counter-clockwise are outer contours and those oriented clockwise are holes. It is up to the user to match each hole to its parent in order to reconstruct the parent-hole relationship of the conceptual output. It is sufficient to test each hole against each parent as there won't be a hole inside a hole, a parent inside any other contour, or a hole inside more than one parent. The recommended insideness test is to perform a regularized Boolean set operation. *do_intersect* from the *Boolean Set Operations* package will work fine in our case since it is guaranteed that no hole would cross halfway outside any parent (in the presence of such cases, subtracting the parent from the hole works better as it correctly rejects halfway holes).

If there are degenerate, or nearly degenerate vertices; that is, vertices whose internal or external angle approaches 0, numerical overflow may prevent some of the polygon contours to be constructed. If that happens, the failed contour just won't be added into the resulting sequence.

PolygonOffsetBuilderTraits_2

CGAL::Polygon_offset_builder_traits_2<Kernel>

CGAL::compute_outer_frame_margin

Definition

The function `compute_outer_frame_margin` computes the separation required between a polygon and the outer frame used to obtain an exterior skeleton suitable for the computation of outer offset polygons at a given distance.

```
#include <CGAL/compute_outer_frame_margin.h>
```

```
template <class InputIterator, class Traits>
boost::optional< typename Traits::FT >
```

```
compute_outer_frame_margin( InputIterator first,
                             InputIterator beyond,
                             typename Traits::FT offset,
                             Traits traits = Default_traits)
```

Given a non-degenerate strictly-simple 2D polygon whose vertices are passed in the range `[first,beyond)`, calculates the largest euclidean distance d between each input vertex and its corresponding offset vertex at a distance `offset`.

If such a distance can be approximately computed, returns an `optional<FT>` with the value $d + (\text{offset} * 1.05)$. If the distance cannot be computed, not even approximately, due to overflow for instance, returns an empty `optional<FT>` (an *absent result*).

This result is the required separation between the input polygon and the rectangular frame used to construct an exterior offset contour at distance `offset` (which is done by placing the polygon as a hole of that frame).

Such a separation must be computed in this way because if the frame is too close to the polygon, the inward offset contour from the frame could collide with the outward offset contour of the polygon, resulting in a merged contour offset instead of two contour offsets, one of them corresponding to the frame.

Simply using $2 * \text{offset}$ as the separation is incorrect since `offset` is the distance between an offset line and its original, not between an offset vertex and its original. The later, which is calculated by this function and needed to place the frame sufficiently away from the polygon, can be thousands of times larger than `offset`.

If the result is *absent*, any attempt to construct an exterior offset polygon at distance `offset` will fail. This will occur whenever the polygon has a vertex with an internal angle approaching 0 (because the offset vertex of a vertex whose internal angle equals 0 is at *infinity*).

Precondition: `offset > 0`.

Precondition: The range `[first,beyond)` contains the vertices of a non-degenerate strictly-simple 2D polygon.

The default traits class *Default_traits* is an instance of the class *Polygon_offset_builder_traits_2<Kernel>* parameterized on the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* is equivalent to *Traits::Point_2*.
2. *Traits* must be a model for *PolygonOffsetBuilderTraits_2*

17.1 Introduction

Given a set C of planar curves, the *arrangement* $\mathcal{A}(C)$ is the subdivision of the plane into zero-dimensional, one-dimensional and two-dimensional cells, called *vertices*, *edges* and *faces*, respectively induced by the curves in C . Arrangements are ubiquitous in the computational-geometry literature and have many applications; see, e.g., [AS00, Hal04].

The curves in C can intersect each other (a single curve may also be self-intersecting or may be comprised of several disconnected branches) and are not necessarily x -monotone.¹ We construct a collection C'' of x -monotone subcurves that are pairwise disjoint in their interiors in two steps as follows. First, we decompose each curve in C into maximal x -monotone subcurves (and possibly isolated points), obtaining the collection C' . Note that an x -monotone curve cannot be self-intersecting. Then, we decompose each curve in C' into maximal connected subcurves not intersecting any other curve (or point) in C' . The collection C'' may also contain isolated points, if the curves of C contain such points. The arrangement induced by the collection C'' can be conveniently embedded as a planar graph, whose vertices are associated with curve endpoints or with isolated points, and whose edges are associated with subcurves. It is easy to see that $\mathcal{A}(C) = \mathcal{A}(C'')$. This graph can be represented using a *doubly-connected edge list* data-structure (DCEL for short), which consists of containers of vertices, edges and faces and maintains the incidence relations among these objects.

The main idea behind the DCEL data-structure is to represent each edge using a pair of directed *halfedges*, one going from the xy -lexicographically smaller (left) endpoint of the curve toward its the xy -lexicographically larger (right) endpoint, and the other, known as its *twin* halfedge, going in the opposite direction. As each halfedge is directed, we say it has a *source* vertex and a *target* vertex. Halfedges are used to separate faces, and to connect vertices (with the exception of *isolated vertices*, which are unconnected).

If a vertex v is the target of a halfedge e , we say that v and e are *incident* to each other. The halfedges incident to a vertex v form a circular list oriented in a clockwise order around this vertex. (An isolated vertex has no incident halfedges.)

Each halfedge e stores a pointer to its *incident face*, which is the face lying to its left. Moreover, every halfedge is followed by another halfedge sharing the same incident face, such that the target vertex of the halfedge is the same as the source vertex of the next halfedge. The halfedges are therefore connected in circular lists, and form chains, such that all edges of a chain are incident to the same face and wind along its boundary. We call such a chain a *connected component of the boundary* (or *CCB* for short).

The unique CCB of halfedges winding in a counterclockwise orientation along a face boundary is referred to as the *outer CCB* of the face. Exactly one unbounded face exists in every arrangement, as the arrangement package supports only bounded curves at this point. The unbounded face does not have an outer boundary. Any other connected component of the boundary of the face is called a *hole* (or *inner CCB*), and can be represented as a circular chain of halfedges winding in a clockwise orientation around it. Note that a hole does not necessarily

¹A continuous planar curve C is *x-monotone* if every vertical line intersects it at most once. For example, a non-vertical line segment is always x -monotone and so is the graph of any continuous function $y = f(x)$. For convenience, we treat vertical line segments as *weakly x-monotone*, as there exists a single vertical line that overlaps them. A circle of radius r centered at (x_0, y_0) is not x -monotone, as the vertical line $x = x_0$ intersects it at $(x_0, y_0 - r)$ and at $(x_0, y_0 + r)$.

Figure 17.1: An arrangement of interior-disjoint line segments with some of the DCEL records that represent it. The unbounded face f_0 has a single connected component that forms a hole inside it, and this hole is comprised of several faces. The half-edge e is directed from its source vertex v_1 to its target vertex v_2 . This edge, together with its twin e' , correspond to a line segment that connects the points associated with v_1 and v_2 and separates the face f_1 from f_2 . The predecessor e_{prev} and successor e_{next} of e are part of the chain that form the outer boundary of the face f_2 . The face f_1 has a more complicated structure as it contains two holes in its interior: One hole consists of two adjacent faces f_3 and f_4 , while the other hole is comprised of two edges. f_1 also contains two isolated vertices u_1 and u_2 in its interior.

correspond to a single face, as it may have no area, or alternatively it may consist of several connected faces. Every face can have several holes contained in its interior (or no holes at all). In addition, every face may contain isolated vertices in its interior. See Figure 17.1 for an illustration of the various DCEL features. For more details on the DCEL data structure see [dBvKOS00, Chapter 2].

The rest of this chapter is organized as follows: In Section 17.2 we review in detail the interface of the *Arrangement_2* class-template, which is the central component in the arrangement package. In Section 17.3 we show how queries on an arrangement can be issued. In Section 17.4 we review some important free (global) functions that operate on arrangements, the most important ones being the free insertion-functions. Section 17.5 contains detailed descriptions of the various geometric traits classes included in the arrangement package. Using these traits classes it is possible to construct arrangements of different families of curves. In Section 17.6 we review the notification mechanism that allows external classes to keep track of the changes that an arrangement instance goes through. Section 17.7 explains how to extend the DCEL records, to store extra data with them, and to efficiently update this data. In Section 17.8 we introduce the fundamental operation of overlaying two arrangements. Section 17.9 describes the *Arrangement_with_history_2* class-template that extends the arrangement by storing additional history records with its curves. Finally, in Section 17.10 we review the arrangement input/output functions.

17.2 The Main Arrangement Class

The class *Arrangement_2*<Traits,Dcel> is the main class in the arrangement package. It is used to represent planar arrangements and provides the interface needed to construct them, traverse them, and maintain them. An arrangement is defined by a geometric *traits* class that determines the family of planar curves that form the

arrangement, and a DCEL class, which represents the *topological structure* of the planar subdivision. It supplies a minimal set of geometric operations (predicates and constructions) required to construct and maintain the arrangement and to operate on it.

The design of the arrangement package is guided by the need to separate between the representation of the arrangements and the various geometric algorithms that operate on them, and by the need to separate between the topological and geometric aspects of the planar subdivision. The separation is exhibited by the two template parameters of the *Arrangement_2* template:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits_2* concept. The traits class defines the types of *x-monotone curves* and two-dimensional points, *X_monotone_curve_2* and *Point_2* respectively, and supports basic geometric predicates on them.

In the first sections of this chapter we always use *Arr_segment_traits_2* as our traits class, to construct arrangements of line segments. However, the arrangement package contains several other traits classes that can handle also polylines (continuous piecewise-linear curves), conic arcs, and arcs of rational functions. We exemplify the usage of these traits classes in Section 17.5.

- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is *Arr_default_dcel<Traits>* by default. However, in many applications it is necessary to extend the DCEL features; see Section 17.7 for further explanations and examples.

17.2.1 A Simple Program

The simple program listed below constructs a planar map of three line segments forming a triangle. The constructed arrangement is instantiated with the *Arr_segment_traits_2* traits class to handle segments only. The resulting arrangement consists of two faces, a bounded triangular face and the unbounded face. The program is not very useful as it is, since it ends immediately after the arrangement is constructed. We give more enhanced examples in the rest of this chapter.

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>      Number_type;
typedef CGAL::Cartesian<Number_type>        Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2                   Point_2;
typedef Traits_2::X_monotone_curve_2        Segment_2;
typedef CGAL::Arrangement_2<Traits_2>       Arrangement_2;

int main()
{
    Arrangement_2    arr;
    Segment_2        cv[3];
    Point_2           p1 (0, 0), p2 (0, 4), p3 (4, 0);

    cv[0] = Segment_2 (p1, p2);
    cv[1] = Segment_2 (p2, p3);
    cv[2] = Segment_2 (p3, p1);
}
```

```

    insert (arr, &cv[0], &cv[3]);

    return (0);
}

```

17.2.2 Traversing the Arrangement

The simplest and most fundamental arrangement operations are the various traversal methods, which allow users to systematically go over the relevant features of the arrangement at hand.

As mentioned above, the arrangement is represented as a DCEL, which stores three containers of vertices, halfedges and faces. Thus, the *Arrangement_2* class supplies iterators for these containers. For example, the methods *vertices_begin()* and *vertices_end()* return *Arrangement_2::Vertex_iterator* objects that define the valid range of arrangement vertices. The value type of this iterator is *Arrangement_2::Vertex*. Moreover, the vertex-iterator type is equivalent to *Arrangement_2::Vertex_handle*, which serves as a pointer to a vertex. As we show next, all functions related to arrangement features accept handle types as input parameters and return handle types as their output.

In addition to the iterators for arrangement vertices, halfedges and faces, the arrangement class also provides *edges_begin()* and *edges_end()* that return *Arrangement_2::Edge_iterator* objects for traversing the arrangement edges. Note that the value type of this iterator is *Arrangement_2::Halfedge*, representing one of the twin halfedges that represent the edge.

All iterator, circulator² and handle types also have non-mutable (*const*) counterparts. These non-mutable iterators are useful to traverse an arrangement without changing it. For example, the arrangement has a non-constant member function called *vertices_begin()* that returns a *Vertex_iterator* object and another *const* member function that returns a *Vertex_const_iterator* object. In fact, all methods listed in this section that return an iterator, a circulator or a handle have non-mutable counterparts. It should be noted that, for example, *Vertex_handle* can be readily converted into a *Vertex_const_handle*, but not vice-verse.

Conversion of a non-mutable handle to a corresponding mutable handle are nevertheless possible, and can be performed using the static function *Arrangement_2::non_const_handle()* (see, e.g., Section 17.3.1). There are three variant of this function, one for each type of handle.

Traversal Methods for an Arrangement Vertex

A vertex is always associated with a geometric entity, namely with a *Point_2* object, which can be obtained by the *point()* method of the *Vertex* class nested within *Arrangement_2*.

The *is_isolated()* method determines whether a vertex is isolated or not. Recall that the halfedges incident to a non-isolated vertex, namely the halfedges that share a common target vertex, form a circular list around this vertex. The *incident_halfedges()* method returns a circulator of type *Arrangement_2::Halfedge_around_vertex_circulator* that enables the traversal of this circular list in a clockwise direction. The value type of this circulator is *Halfedge*.

The following function prints all the neighbors of a given arrangement vertex (assuming that the *Point_2* type can be inserted into the standard output using the << operator). The arrangement type is the same as in the simple example above.

```

void print_neighboring_vertices (Arrangement_2::Vertex_const_handle v)

```

²A *circulator* is used to traverse a circular list, such as the list of halfedges incident to a vertex — see below.

```

{
    if (v->is_isolated()) {
        std::cout << "The vertex (" << v->point() << ") is isolated" << std::endl;
        return;
    }

    Arrangement_2::Halfedge_around_vertex_const_circulator first, curr;
    first = curr = v->incident_halfedges();

    std::cout << "The neighbors of the vertex (" << v->point() << ") are:";
    do {
        // Note that the current halfedge is directed from u to v:
        Arrangement_2::Vertex_const_handle u = curr->source();
        std::cout << " (" << u->point() << ")";
    } while (++curr != first);
    std::cout << std::endl;
}

```

In case of an isolated vertex, it is possible to obtain the face that contains this vertex using the *face()* method.

Traversal Methods for an Arrangement Halfedge

Each arrangement edge, realized as a pair of twin halfedges, is associated with an *X_monotone_curve_2* object, which can be obtained by the *curve()* method of the *Halfedge* class nested in the *Arrangement_2* class.

The *source()* and *target()* methods return handles to the halfedge source and target vertices respectively. We can obtain a handle to the twin halfedge using the *twin()* method. From the definition of halfedges, it follows that if *he* is a halfedge handle, then:

- *he->curve()* is equivalent to *he->twin()->curve()*,
- *he->source()* is equivalent to *he->twin()->target()*, and
- *he->target()* is equivalent to *he->twin()->source()*.

Every halfedge has an incident face that lies to its left, which can be obtained by the *face()* method. Recall that a halfedge is always one link in a connected chain of halfedges that share the same incident face, known as a *CCB*. The *prev()* and *next()* methods return handles to the previous and next halfedges in the CCB respectively.

As the CCB is a circular list of halfedges, it is only natural to traverse it using a circulator. The *ccb()* method returns a *Arrangement_2::Ccb_halfedge_circulator* object for the halfedges along the CCB.

The function *print_ccb()* listed below prints all *x-monotone* curves along a given CCB (assuming that the *Point_2* and the *X_monotone_curve_2* types can be inserted into the standard output using the *<<* operator).

```

void print_ccb (Arrangement_2::Ccb_halfedge_const_circulator circ)
{
    Ccb_halfedge_const_circulator curr = circ;
    std::cout << "(" << curr->source()->point() << ")";
    do {
        Arrangement_2::Halfedge_const_handle he = curr->handle();
        std::cout << " [" << he->curve() << "]" "

```

```

        << "(" << he->target()->point() << ")";
    } while (++curr != circ);
    std::cout << std::endl;
}

```

Traversal Methods for an Arrangement Face

An arrangement of bounded curves always has a single unbounded face. The function *unbounded_face()* returns a handle to this face. (Note that an empty arrangement contains nothing *but* the unbounded face.)

Given a *Face* object, we can use the *is_unbounded()* method to determine whether it is unbounded. Bounded faces have an outer CCB, and the *outer_ccb()* method returns a circulator for the halfedges along this CCB. Note that the halfedges along this CCB wind in a counterclockwise orientation around the outer boundary of the face.

A face can also contain disconnected components in its interior, namely holes and isolated vertices:

- The *holes_begin()* and *holes_end()* methods return *Arrangement_2::Hole_iterator* iterators that define the range of holes inside the face. The value type of this iterator is *Ccb_halfedge_circulator*, defining the CCB that winds in a clockwise orientation around a hole.
- The *isolated_vertices_begin()* and *isolated_vertices_end()* methods return *Arrangement_2::Isolated_vertex_iterator* iterators that define the range of isolated vertices inside the face. The value type of this iterator is *Vertex*.

The function *print_face()* listed below prints the outer and inner boundaries of a given face, using the function *print_ccb()*, which was introduced in the previous subsection.

```

void print_face (Arrangement_2::Face_const_handle f)
{
    // Print the outer boundary.
    if (f->is_unbounded())
        std::cout << "Unbounded face. " << std::endl;
    else {
        std::cout << "Outer boundary: ";
        print_ccb (f->outer_ccb());
    }

    // Print the boundary of each of the holes.
    Arrangement_2::Hole_const_iterator hi;
    int index = 1;
    for (hi = f->holes_begin(); hi != f->holes_end(); ++hi, ++index) {
        std::cout << "    Hole #" << index << ": ";
        print_ccb (*hi);
    }

    // Print the isolated vertices.
    Arrangement_2::Isolated_vertex_const_iterator iv;
    for (iv = f->isolated_vertices_begin(), index = 1;
         iv != f->isolated_vertices_end(); ++iv, ++index)
    {
        std::cout << "    Isolated vertex #" << index << ": "
                  << "(" << iv->point() << ")" << std::endl;
    }
}

```

```
}
}
```

Additional Example

The function listed below prints the current setting of a given arrangement. This concludes the preview of the various traversal methods.³

```
void print_arrangement (const Arrangement_2& arr)
{
    // Print the arrangement vertices.
    Vertex_const_iterator vit;
    std::cout << arr.number_of_vertices() << " vertices:" << std::endl;
    for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
        std::cout << "(" << vit->point() << ")";
        if (vit->is_isolated())
            std::cout << " - Isolated." << std::endl;
        else
            std::cout << " - degree " << vit->degree() << std::endl;
    }

    // Print the arrangement edges.
    Edge_const_iterator eit;
    std::cout << arr.number_of_edges() << " edges:" << std::endl;
    for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit)
        std::cout << "[" << eit->curve() << "]" << std::endl;

    // Print the arrangement faces.
    Face_const_iterator fit;
    std::cout << arr.number_of_faces() << " faces:" << std::endl;
    for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit)
        print_face (fit);
}
```

17.2.3 Modifying the Arrangement

In this section we review the various member functions of the *Arrangement_2* class that allow users to modify the topological structure of the arrangement by introducing new edges or vertices, modifying them, or removing them.

The arrangement member-functions that insert new curves into the arrangement, thus enabling the construction of a planar subdivision, are rather specialized, as they require a-priori knowledge on the location of the inserted curve. Indeed, for most purposes it is more convenient to construct an arrangement using the free (global) insertion-functions.

³The file *arr_print.h*, which can be found under the examples folder, includes this function and the rest of the functions listed in this section. Over there they are written in a more generic fashion, where the arrangement type serves as a template parameter for these functions, so different instantiations of the *Arrangement_2<Traits,Dcel>* template can be provided to the same function templates.

Figure 17.2: The various specialized insertion procedures. The inserted x -monotone curve is drawn with a light dashed line, surrounded by two solid arrows that represent the pair of twin half-edges added to the DCEL. Existing vertices are shown as black dots while new vertices are shown as light dots. Existing half-edges that are affected by the insertion operations are drawn as dashed arrows. (a) Inserting a curve as a new hole inside the face f . (b) Inserting a curve from an existing vertex u that corresponds to one of its endpoints. (c) Inserting an x -monotone curve whose endpoints are the already existing vertices u_1 and u_2 . In our case, the new pair of half-edges close a new face f' , where the hole h_1 , which used to belong to f , now becomes an enclave in this new face.

Inserting Non-Intersecting x -Monotone Curves

The most important functions that allow users to modify the arrangement, and perhaps the most frequently used ones, are the specialized insertion functions of x -monotone curves whose interior is disjoint from any other curve in the existing arrangement and do not contain any vertex of the arrangement. In addition, these function require that the location of the curve in the arrangement is known.

The motivation behind these rather harsh restrictions on the nature of the inserted curves is the decoupling of the topological arrangement representation from the various algorithms that operate on it. While the insertion of an x -monotone curve whose interior is disjoint from all existing arrangement features is quite straightforward (as we show next), inserting curves that intersect with the curves already inserted into the arrangement is much more complicated and requires the application of non-trivial geometric algorithms. These insertion operations are therefore implemented as free functions that operate on the arrangement and the inserted curve(s); see Section 17.4 for more details and examples.⁴

When an x -monotone curve is inserted into an existing arrangement, such that the interior of this curve is disjoint from any arrangement feature, only the following three scenarios are possible, depending on the status of the endpoints of the inserted subcurve:

1. In case both curve endpoints do not correspond to any existing arrangement vertex we have to create two new vertices corresponding to the curve endpoints and connect them using a pair of twin halfedges. This halfedge pair initiates a new hole inside the face that contains the curve in its interior.
2. If exactly one endpoint corresponds to an existing arrangement vertex (we distinguish between a vertex that corresponds to the left endpoint of the inserted curve and a vertex corresponding to its right endpoint), we have to create a new vertex that corresponds to the other endpoint of the curve and to connect the two vertices by a pair of twin halfedges that form an “antenna” emanating from the boundary of an existing connected component (note that if the existing vertex used to be isolated, this operation is actually equivalent to forming a new hole inside the face that contains this vertex).

⁴You may skip to Section 17.4, and return to this subsection at a later point in time.

Figure 17.3: The arrangement of the line segments s_1, \dots, s_5 constructed in *ex_edge_insertion.C*. The arrows mark the direction of the halfedges returned from the various insertion functions.

3. If both endpoints correspond to existing arrangement vertices, we connect these vertices using a pair of twin halfedges. (If one or both vertices are isolated this case reduces to one of the two previous cases respectively.) The two following subcases may occur:

- Two disconnected components are merged into a single connected component (as is the case with the segment s_1 in the figure to the left).
- A new face is created, a face that splits from an existing arrangement face. In this case we also have to examine the holes and isolated vertices in the existing face and move the relevant ones inside the new face (as is the case with the segment s_2 in the figure to the left).

The *Arrangement_2* class offers insertion functions named *insert_in_face_interior()*, *insert_from_left_vertex()*, *insert_from_right_vertex()* and *insert_at_vertices()* that perform the special insertion procedures listed above. The first function accepts an x -monotone curve c and an arrangement face f that contains this curve in its interior. The other functions accept an x -monotone curve c and handles to the existing vertices that correspond to the curve endpoint(s). Each of the four functions returns a handle to one of the twin halfedges that have been created, where:

- *insert_in_face_interior(c, f)* returns a halfedge directed from the vertex corresponding to the left endpoint of c toward the vertex corresponding to its right endpoint.
- *insert_from_left_vertex(c, v)* and *insert_from_right_vertex(c, v)* returns a halfedge whose source is the vertex v that and whose target is the new vertex that has just been created.
- *insert_at_vertices(c, v1, v2)* returns a halfedge directed from v_1 to v_2 .

The following program demonstrates the usage of the four insertion functions. It creates an arrangement of five line segments, as depicted in Figure 17.3.⁵ As the arrangement is very simple, we use the simple Cartesian kernel of CGAL with integer coordinates for the segment endpoints. We also use the *Arr_segment_traits_2* class that enables the efficient maintenance of arrangements of line segments; see more details on this traits class

⁵Notice that in all figures in the rest of this chapter the coordinate axes are drawn only for illustrative purposes and are *not* part of the arrangement.

in Section 17.5. This example, as many others in this chapter, uses some print-utility functions from the file *print_arr.h*; these functions are also listed in Section 17.2.2.

```

//! \file examples/Arrangement_2/ex_edge_insertion.C
// Constructing an arrangement using the simple edge-insertion functions.

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/IO/Arr_istream.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::X_monotone_curve_2          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef Arrangement_2::Vertex_handle           Vertex_handle;
typedef Arrangement_2::Halfedge_handle         Halfedge_handle;

int main ()
{
    Arrangement_2    arr;

    Segment_2        s1 (Point_2 (1, 3), Point_2 (3, 5));
    Segment_2        s2 (Point_2 (3, 5), Point_2 (5, 3));
    Segment_2        s3 (Point_2 (5, 3), Point_2 (3, 1));
    Segment_2        s4 (Point_2 (3, 1), Point_2 (1, 3));
    Segment_2        s5 (Point_2 (1, 3), Point_2 (5, 3));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1, arr.unbounded_face());
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_left_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_from_right_vertex (s3, v3);
    Vertex_handle   v4 = e3->target();
    Halfedge_handle e4 = arr.insert_at_vertices (s4, v4, v1);
    Halfedge_handle e5 = arr.insert_at_vertices (s5, v1, v3);

    print_arrangement (arr);
    return (0);
}

```

Observe that the first line segment is inserted in the interior of the unbounded face. The other line segments are inserted using the vertices created by the insertion of previous segments. The resulting arrangement consists of three faces, where the two bounded faces form together a hole in the unbounded face.

Figure 17.4: An arrangement of line segments containing three isolated vertices, as constructed in *ex_isolated_vertices.C*. The vertices u_2 and u_3 are eventually removed from the arrangement.

Manipulating Isolated Vertices

Isolated points are in general simpler geometric entities than curves and indeed the member functions that manipulate them are easier to understand.

The function *insert_in_face_interior*(p, f) inserts an isolated point p , located in the interior of a given face f , into the arrangement and returns a handle to the arrangement vertex it has created and associated with p . Naturally, this function has a precondition that p is really an isolated point, namely it does not coincide with any existing arrangement vertex and does not lie on any edge. As mentioned in Section 17.2.2, it is possible to obtain the face containing an isolated vertex handle v by calling $v \rightarrow \text{face}()$.

The function *remove_isolated_vertex*(v) receives a handle to an isolated vertex and removes it from the arrangement.

The following program demonstrates the usage of the arrangement member-functions for manipulating isolated vertices. It first inserts three isolated vertices located inside the unbounded face, then it inserts four line segments that form a rectangular hole inside the unbounded face (see Figure 17.4 for an illustration). Finally, it traverses the vertices and removes those isolated vertices that are still contained in the unbounded face (u_2 and u_3 in this case):

```

//! \file examples/Arrangement_2/ex_isolated_vertices.C
// Constructing an arrangement with isolated vertices.

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;

```

```

typedef CGAL::Arrangement_2<Traits_2>           Arrangement_2;
typedef Arrangement_2::Vertex_handle           Vertex_handle;
typedef Arrangement_2::Halfedge_handle         Halfedge_handle;
typedef Arrangement_2::Face_handle             Face_handle;

int main ()
{
    Arrangement_2  arr;

    // Insert some isolated points:
    Face_handle     uf = arr.unbounded_face();
    Vertex_handle   u1 = arr.insert_in_face_interior (Point_2 (3, 3), uf);
    Vertex_handle   u2 = arr.insert_in_face_interior (Point_2 (1, 5), uf);
    Vertex_handle   u3 = arr.insert_in_face_interior (Point_2 (5, 5), uf);

    // Insert four segments that form a rectangular face:
    Segment_2       s1 (Point_2 (1, 3), Point_2 (3, 5));
    Segment_2       s2 (Point_2 (3, 5), Point_2 (5, 3));
    Segment_2       s3 (Point_2 (5, 3), Point_2 (3, 1));
    Segment_2       s4 (Point_2 (3, 1), Point_2 (1, 3));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1, uf);
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_left_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_from_right_vertex (s3, v3);
    Vertex_handle   v4 = e3->target();
    Halfedge_handle e4 = arr.insert_at_vertices (s4, v4, v1);

    // Remove the isolated vertices located in the unbounded face.
    Arrangement_2::Vertex_iterator  curr_v, next_v;

    for (curr_v = arr.vertices_begin();
         curr_v != arr.vertices_end(); curr_v = next_v)
    {
        // Store an iterator to the next vertex (as we may delete curr_v and
        // invalidate the iterator).
        next_v = curr_v;
        ++next_v;

        if (curr_v->is_isolated() && curr_v->face() == uf)
            arr.remove_isolated_vertex (curr_v);
    }

    print_arrangement (arr);
    return (0);
}

```

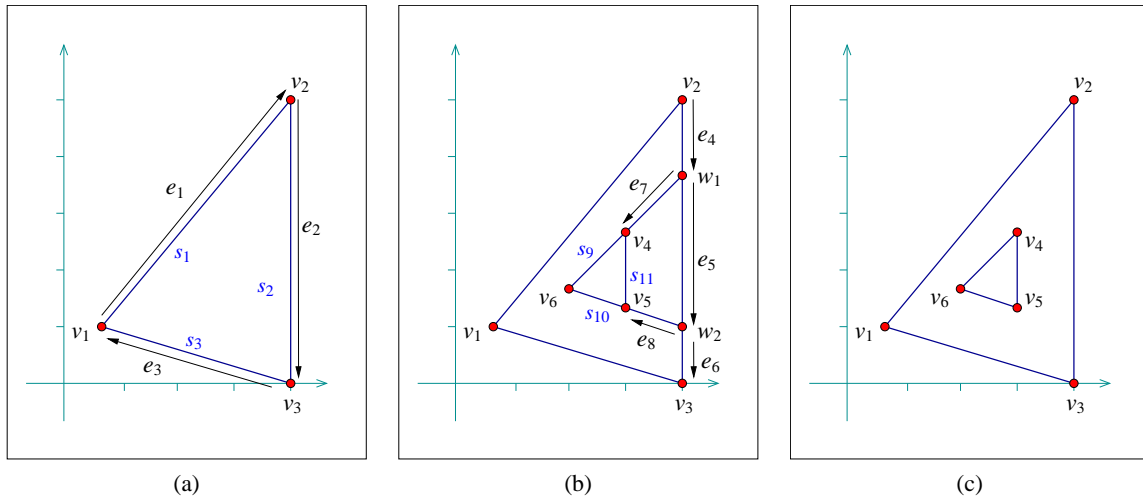

Figure 17.5: An arrangement of line segments as constructed in *ex_edge_manipulation.C*. Note that the edges e_7 and e_8 and the vertices w_1 and w_2 , introduced in step (b) are eventually removed in step (c).

Manipulating Halfedges

In the previous subsection we showed how to introduce new isolated vertices in the arrangement. But how does one create a vertex that lies on an existing arrangement edge (more precisely, on an x -monotone curve that is associated with an arrangement edge)?

It should be noted that such an operation involves the splitting of a curve at a given point in its interior, while the traits class used by *Arrangement_2* does not necessarily have the ability to perform such a split operation. However, if users have the ability to split an x -monotone curve into two at a given point p (this is usually the case when employing a more sophisticated traits class; see Section 17.5 for more details) they can use the *split_edge*(e , c_1 , c_2) function, where c_1 and c_2 are the two subcurves resulting from splitting the x -monotone curve associated with the halfedge e at some point (call it p) in its interior. The function splits the halfedge pair into two pairs, both incident to a new vertex v associated with p , and returns a handle to a halfedge whose source equals e 's source vertex and whose target is the new vertex v .

The reverse operation is also possible. Suppose that we have a vertex v of degree 2, whose two incident halfedges, e_1 and e_2 , are associated with the curves c_1 and c_2 . Suppose further that it is possible to merge these two curves into a single continuous x -monotone curve c . Calling *merge_edge*(e_1 , e_2 , c) will merge the two edges into a single edge associated with the curve c , essentially removing the vertex v from the arrangement.

Finally, the function *remove_edge*(e) removes the edge e from the arrangement. Note that this operation is the reverse of an insertion operation, so it may cause a connected component to split into two, or two faces to merge into one, or a hole to disappear. By default, if the removal of e causes one of its end-vertices to become isolated, we remove this vertex as well. However, users can control this behavior and choose to keep the isolated vertices by supplying additional Boolean flags to *remove_edge*() indicating whether the source and the target vertices are to be removed should they become isolated.

In the following example program we show how the edge-manipulation functions can be used. The program works in three steps, as demonstrated in Figure 17.5. Note that here we still stick to integer coordinates, but as we work on a larger scale we use an unbounded integer number-type (in this case, the *Gmpz* type taken from the GMP library) instead of the built-in *int* type.⁶ In case the GMP library is not installed (as indicated

⁶As a rule of thumb, one can use a bounded integer type for representing line segments whose coordinates are bounded by $\lfloor \sqrt[3]{M} \rfloor$, where M is the maximal representable integer value. This guarantees that no overflows occur in the computations carried out by the traits class, hence all traits-class predicates always return correct results.

by the *CGAL_USE_GMP* flag defined in *CGAL/basic.h*), we use *MP_Float*, a number-type included in CGAL's support library that is capable of storing floating-point numbers with unbounded mantissa. We also use the standard Cartesian kernel of CGAL as our kernel. This is recommended when the kernel is instantiated with a more complex number type, as we demonstrate in other examples in this chapter.

```

//! \file examples/Arrangement_2/ex_edge_manipulation.C
// Using the edge-manipulation functions.

#include <CGAL/basic.h>

#ifdef CGAL_USE_GMP
    #include <CGAL/Gmpz.h>
    typedef CGAL::Gmpz                                Number_type;
#else
    #include <CGAL/MP_Float.h>
    typedef CGAL::MP_Float                            Number_type;
#endif

#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>                  Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>            Traits_2;
typedef Traits_2::Point_2                             Point_2;
typedef Traits_2::X_monotone_curve_2                  Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                 Arrangement_2;
typedef Arrangement_2::Vertex_handle                  Vertex_handle;
typedef Arrangement_2::Halfedge_handle                 Halfedge_handle;

int main ()
{
    // Step (a) - construct a triangular face.
    Arrangement_2  arr;

    Segment_2      s1 (Point_2 (667, 1000), Point_2 (4000, 5000));
    Segment_2      s2 (Point_2 (4000, 0), Point_2 (4000, 5000));
    Segment_2      s3 (Point_2 (667, 1000), Point_2 (4000, 0));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1, arr.unbounded_face());
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_right_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_at_vertices (s3, v3, v1);

    // Step (b) - create additional two faces inside the triangle.
    Point_2        p1 (4000, 3666), p2 (4000, 1000);
    Segment_2      s4 (Point_2 (4000, 5000), p1);
    Segment_2      s5 (p1, p2);
    Segment_2      s6 (Point_2 (4000, 0), p2);

```

```

Halfedge_handle e4 = arr.split_edge (e2, s4,
                                     Segment_2 (Point_2 (4000, 0), p1));
Vertex_handle   w1 = e4->target();
Halfedge_handle e5 = arr.split_edge (e4->next(), s5, s6);
Vertex_handle   w2 = e5->target();
Halfedge_handle e6 = e5->next();

Segment_2       s7 (p1, Point_2 (3000, 2666));
Segment_2       s8 (p2, Point_2 (3000, 1333));
Segment_2       s9 (Point_2 (3000, 2666), Point_2 (2000, 1666));
Segment_2       s10 (Point_2 (3000, 1333), Point_2 (2000, 1666));
Segment_2       s11 (Point_2 (3000, 1333), Point_2 (3000, 2666));

Halfedge_handle e7 = arr.insert_from_right_vertex (s7, w1);
Vertex_handle   v4 = e7->target();
Halfedge_handle e8 = arr.insert_from_right_vertex (s8, w2);
Vertex_handle   v5 = e8->target();
Vertex_handle   v6 = arr.insert_in_face_interior (Point_2 (2000, 1666),
                                                  e8->face());

arr.insert_at_vertices (s9, v4, v6);
arr.insert_at_vertices (s10, v5, v6);
arr.insert_at_vertices (s11, v4, v5);

// Step (c) - remove and merge faces to form a single hole in the triangle.
arr.remove_edge (e7);
arr.remove_edge (e8);

e5 = arr.merge_edge (e5, e6, Segment_2 (e5->source()->point(),
                                         e6->target()->point()));
e2 = arr.merge_edge (e4, e5, s2);

print_arrangement (arr);
return (0);
}

```

Note how we use the halfedge handles returned from *split_edge()* and *merge_edge()*. Also note the insertion of the isolated vertex v_6 located inside the triangular face (the incident face of e_7). This vertex seizes from being isolated, as it is gets connected to other vertices.

In this context, we should mention the two member functions *modify_vertex(v, p)*, which sets p to be the point associated with the vertex v , and *modify_edge(e, c)*, which sets c to be the x -monotone curve associated with the halfedge e . These functions have preconditions that p is geometrically equivalent to $v \rightarrow \text{point}()$ and c is equivalent to $e \rightarrow \text{curve}()$ (i.e., the two curves have the same graph), respectively, to avoid the invalidation of the geometric structure of the arrangement. At a first glance it may seem as these two functions are of little use. However, we should keep in mind that there may be extraneous data (probably non-geometric) associated with the point objects or with the curve objects, as defined by the traits class. With these two functions we can modify this data; see more details in Section 17.5.

In addition, we can use these functions to replace a geometric object (a point or a curve) with an equivalent object that has a more compact representation. For example, we can replace the point $(\frac{20}{40}, \frac{99}{33})$ associated with some vertex v , by $(\frac{1}{2}, 3)$.

Figure 17.6: An arrangement of line segments, as constructed in *ex_special_edge_insertion.C*. Note that p_0 is initially inserted as an isolated point and later on connected to the other four vertices.

advanced

Advanced Insertion Functions

Assume that the specialized insertion function *insert_from_left_vertex*(c, v) is invoked for a curve c , whose left endpoint is already associated with a non-isolated vertex v . Namely, v has already several incident halfedges. It is necessary in this case to locate the exact place for the new halfedge mapped to the inserted new curve c in the circular list of halfedges incident to v . More precisely, it is sufficient to locate one of the halfedges *pred* directed toward v such that c is located between *pred* and *pred*->next() in clockwise order around v , in order to complete the insertion (see Figure 17.2 for an illustration). This may take $O(d)$ time where d is the degree of the vertex. However, if the halfedge *pred* is known in advance, the insertion can be carried out in constant time.

The *Arrangement_2* class provides the advanced versions of the specialized insertion functions for a curve c — namely we have *insert_from_left_vertex*($c, pred$) and *insert_from_right_vertex*($c, pred$) that accept a halfedge *pred* as specified above, instead of a vertex v . These functions are more efficient, as they take constant time and do not perform any geometric operations. Thus, they should be used when the halfedge *pred* is known. In case that the vertex v is isolated or that the predecessor halfedge for the new inserted curve is not known, the simpler versions of these insertion functions should be used.

Similarly, there exist two overrides of the *insert_at_vertices*() function: One that accept the two predecessor halfedges around the two vertices v_1 and v_2 that correspond to the curve endpoints, and one that accepts a handle for one vertex and a predecessor halfedge around the other vertex.

The following program shows how to construct the arrangement depicted in Figure 17.6 using the specialized insertion functions that accept predecessor halfedges:

```

//! \file examples/Arrangement_2/ex_special_edge_insertion.C
// Constructing an arrangement using the specialized edge-insertion functions.

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>

```

```

#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef Arrangement_2::Vertex_handle           Vertex_handle;
typedef Arrangement_2::Halfedge_handle         Halfedge_handle;

int main ()
{
    Arrangement_2    arr;

    Point_2          p0 (3, 3);
    Point_2          p1 (1, 3), p2 (3, 5), p3 (5, 3), p4 (3, 1);
    Segment_2        s1 (p1, p2);
    Segment_2        s2 (p2, p3);
    Segment_2        s3 (p3, p4);
    Segment_2        s4 (p4, p1);
    Segment_2        s5 (p1, p0);
    Segment_2        s6 (p0, p3);
    Segment_2        s7 (p4, p0);
    Segment_2        s8 (p0, p2);

    Vertex_handle    v0 = arr.insert_in_face_interior (p0, arr.unbounded_face());
    Halfedge_handle  e1 = arr.insert_in_face_interior (s1, arr.unbounded_face());
    Halfedge_handle  e2 = arr.insert_from_left_vertex (s2, e1);
    Halfedge_handle  e3 = arr.insert_from_right_vertex (s3, e2);
    Halfedge_handle  e4 = arr.insert_at_vertices (s4, e3, e1->twin());
    Halfedge_handle  e5 = arr.insert_at_vertices (s5, e1->twin(), v0);
    Halfedge_handle  e6 = arr.insert_at_vertices (s6, e5, e3->twin());
    Halfedge_handle  e7 = arr.insert_at_vertices (s7, e4->twin(), e6->twin());
    Halfedge_handle  e8 = arr.insert_at_vertices (s8, e5, e2->twin());

    print_arrangement (arr);
    return (0);
}

```

It is possible to perform even more refined operations on an *Arrangement_2* instance given specific topological information. As most of these operations are very fragile and perform no precondition testing on their input in order to gain efficiency, they are not included in the public interface of the arrangement class. Instead, the *Arr_accessor<Arrangement>* class allows access to these internal arrangement operations — see more details in the Reference Manual.

advanced

17.3 Issuing Queries on an Arrangement

One of the most important query types defined on arrangements is the *point-location* query: Given a point, find the arrangement cell that contains it. Typically, the result of a point-location query is one of the arrangement faces, but in degenerate situations the query point can be located on an edge or coincide with a vertex.

Point-location queries are not only common in many applications, they also play an important role in the free insertion-functions (see Section 17.4). Therefore, it is crucial to have the ability to answer such queries effectively for any arrangement instance.

17.3.1 Point-Location Queries

The arrangement package includes several classes (more precisely, class templates parameterized by an arrangement class) that model the *ArrangementPointLocation_2* concept. Namely, they all have a member function called *locate(q)* that accepts a query point *q* and result with a CGAL *Object* that wraps a handle to the arrangement cell containing the query point. This object can be assigned to either a *Face_const_handle*, *Halfedge_const_handle* or a *Vertex_const_handle*, depending on whether the query point is located inside a face, on an edge or on a vertex.

Note that the handles returned by the *locate()* functions are *const* (non-mutable) handles. If necessary, such handles may be casted to mutable handles using the static functions *Arrangement_2::non_const_handle()* provided by the arrangement class.

An instance of any point-location class must be attached to an *Arrangement_2* instance so we can use it to issue point-location queries. This attachment can be performed when the point-location instance is constructed, or at a later time, using the *init(arr)* method, where *arr* is the attached *Arrangement_2* instance. In this chapter we always use the first option.

The following function template, which can be found in the example file *point_location_utils.h*, accepts a point-location object (whose type can be any of the models to the *ArrangementPointLocation_2* concept) and a query point, and prints out the result of the point-location query for the given point. Observe how we use the function *CGAL::assign()* in order to cast the resulting *CGAL::Object* into a handle to an arrangement feature. The point-location object *pl* is assumed to be already associated with an arrangement:

```
template <class PointLocation>
void point_location_query
    (const PointLocation& pl,
     const typename PointLocation::Arrangement_2::Point_2& q)
{
    // Perform the point-location query.
    CGAL::Object obj = pl.locate (q);

    // Print the result.
    typedef typename PointLocation::Arrangement_2 Arrangement_2;

    typename Arrangement_2::Vertex_const_handle v;
    typename Arrangement_2::Halfedge_const_handle e;
    typename Arrangement_2::Face_const_handle f;

    std::cout << "The point " << q << " is located ";
    if (CGAL::assign (f, obj)) {
        // q is located inside a face:
```

```

    if (f->is_unbounded())
        std::cout << "inside the unbounded face." << std::endl;
    else
        std::cout << "inside a bounded face." << std::endl;
}
else if (CGAL::assign (e, obj)) {
    // q is located on an edge:
    std::cout << "on an edge: " << e->curve() << std::endl;
}
else if (CGAL::assign (v, obj)) {
    // q is located on a vertex:
    if (v->is_isolated())
        std::cout << "on an isolated vertex: " << v->point() << std::endl;
    else
        std::cout << "on a vertex: " << v->point() << std::endl;
}
else {
    CGAL_assertion_msg (false, "Invalid object.");
}
}

```

Choosing a Point-Location Strategy

Each of the various point-location classes employs a different algorithm or *strategy*⁷ for answering queries:

- *Arr_naive_point_location*<Arrangement> locates the query point naïvely, by exhaustively scanning all arrangement cells.
- *Arr_walk_along_a_line_point_location*<Arrangement> simulates a traversal, in reverse order, along an imaginary vertical ray emanating from the query point: It starts from the unbounded face of the arrangement and moves downward toward the query point until locating the arrangement cell containing it.
- *Arr_landmarks_point_location*<Arrangement, Generator> uses a set of “landmark” points whose location in the arrangement is known. Given a query point, it uses a KD-tree to find the nearest landmark and then traverses the straight line segment connecting this landmark to the query point.

There are various ways to select the landmark set in the arrangement, determined by the *Generator* template parameter. By default, the generator class *Arr_landmarks_vertices_generator* is used and the arrangement vertices are the selected landmarks, but other landmark generators, such as sampling random points or choosing points on a grid, are also available; see the Reference Manual for more details.

- *Arr_trapezoid_ric_point_location*<Arrangement> implements Mulmuley’s point-location algorithm [Mul90] (see also [dBvKOS00, Chapter 6]). The arrangement faces are decomposed into simpler cells of constant complexity known as *pseudo-trapezoids* and a search-structure (a directed acyclic graph) is constructed on top of these cells, allowing to locate the pseudo-trapezoid (hence the arrangement cell) containing a query point in expected logarithmic time.

The main advantage of the first two strategies is that they do not require any extra data, so the respective classes just store a pointer to an arrangement object and operate directly on it. Attaching such point-location objects to an existing arrangement has virtually no running-time cost at all, but the query time is linear in the size of the arrangement (the performance of the “walk” strategy is much better in practice, but its worst-case performance

⁷We use the term *strategy* following the design pattern taxonomy [GHJV95].

Figure 17.7: The arrangement of line segments, as constructed in *ex_point_location.C*, *ex_vertical_ray_shooting.C*, and *ex_batched_point_location.C*. The arrangement vertices are drawn as small discs, while the query points q_1, \dots, q_6 are marked with crosses.

is linear). Using these strategies is therefore recommended only when a relatively small number of point-location queries are issued by the application, or when the arrangement is constantly changing (i.e., changes in the arrangement structure are more frequent than point-location queries).

On the other hand, the landmarks and the trapezoid RIC strategies require auxiliary data structures on top of the arrangement, which they need to construct once they are attached to an arrangement object and need to keep up-to-date as this arrangement changes. The data structures needed by both strategies can be constructed in $O(N \log N)$ time (where N is the overall number of edges in the arrangement), but the construction needed by the landmark algorithm is in practice significantly faster. In addition, although both resulting data structures are asymptotically linear in size, the KD-tree that the landmark algorithm stores needs significantly less memory. We note that Mulmuley's algorithm guarantees a logarithmic query time, while the query time for the landmark strategy is only logarithmic on average — and we may have scenarios where the query time can be linear. In practice however, the query times of both strategies are competitive. For a detailed experimental comparison, see [HH05]

The main drawback in the current implementation of the landmark strategy, compared to the trapezoidal RIC strategy, is that while the updating the auxiliary data structures related to the trapezoidal decomposition is done very efficiently, the KD-tree maintained by the landmark algorithm needs to be frequently rebuilt as the arrangement changes. In addition, using the landmark point-location class adds some extra requirement from the traits class (that is, the traits class should be a model of a refined concept *ArrangementLandmarkTraits_2*; see Section 17.5 for the details). However, most built-in traits classes that come with the CGAL public release support these extra operations.

It is therefore recommended to use the *Arr_landmarks_point_location* class when the application frequently issues point-location queries on an arrangement that only seldom changes. If the arrangement is more dynamic and is frequently going through changes, the *Arr_trapezoid_ric_point_location* class should be the selected point-location strategy.

An Example

The following program constructs a simple arrangement of five line segments that form a pentagonal face, with a single isolated vertex in its interior, as depicted in Figure 17.7 (the arrangement construction is performed by

the function *construct_segment_arr()* whose listing is omitted here and can be found in *point_location_utils.h*). It then employs the naïve and the landmark strategies to issue several point-location queries on this arrangement:

```

//! \file examples/Arrangement_2/ex_point_location.C
// Answering point-location queries.

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>
#include <CGAL/Arr_landmarks_point_location.h>

#include "point_location_utils.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;
typedef CGAL::Arr_landmarks_point_location<Arrangement_2> Landmarks_pl;

int main ()
{
    // Construct the arrangement.
    Arrangement_2    arr;
    Naive_pl         naive_pl (arr);
    Landmarks_pl     landmarks_pl;

    construct_segments_arr (arr);

    // Perform some point-location queries using the naive strategy.
    Point_2          q1 (1, 4);
    Point_2          q2 (4, 3);
    Point_2          q3 (6, 3);

    point_location_query (naive_pl, q1);
    point_location_query (naive_pl, q2);
    point_location_query (naive_pl, q3);

    // Attach the landmarks object to the arrangement and perform queries.
    Point_2          q4 (3, 2);
    Point_2          q5 (5, 2);
    Point_2          q6 (1, 0);

    landmarks_pl.attach (arr);

    point_location_query (landmarks_pl, q4);
    point_location_query (landmarks_pl, q5);
    point_location_query (landmarks_pl, q6);

    return (0);
}

```

Note that the program uses the auxiliary *point_location_query()* function template to nicely print the result of each query. This function can be found in the header file *point_location_utils.h*.

17.3.2 Vertical Ray Shooting

Another important query issued on arrangements is the vertical ray-shooting query: Given a query point, which arrangement feature do we encounter if we shoot a vertical ray emanating upward (or downward) from this point? In the general case the ray hits an edge, but it is possible that it hits a vertex, or that the arrangement does not have any feature lying directly above (or below) the query point.

All point-location classes listed in the previous section are also models of the *ArrangementVerticalRayShoot_2* concept. That is, they all have member functions called *ray_shoot_up(q)* and *ray_shoot_down(q)* that accept a query point *q* and output a CGAL *Object*. This can be assigned to either a *Halfedge_const_handle* or to a *Vertex_const_handle*. Alternatively, the returned value is a *Face_const_handle* for the unbounded face of the arrangement, in case there is no edge or vertex lying directly above (or below) *q*.

The following function template, *vertical_ray_shooting_query()*, which also located in the header file *point_location_utils.h*, accepts a vertical ray-shooting object, whose type can be any of the models to the *ArrangementVerticalRayShoot_2* concept and prints out the result of the upward vertical ray-shooting operations from a given query point. The ray-shooting object *vrs* is assumed to be already associated with an arrangement:

```
template <class VerticalRayShoot>
void vertical_ray_shooting_query
    (const VerticalRayShoot& vrs,
     const typename VerticalRayShoot::Arrangement_2::Point_2& q)
{
    // Perform the point-location query.
    CGAL::Object    obj = vrs.ray_shoot_up (q);

    // Print the result.
    typedef typename VerticalRayShoot::Arrangement_2 Arrangement_2;

    typename Arrangement_2::Vertex_const_handle    v;
    typename Arrangement_2::Halfedge_const_handle  e;
    typename Arrangement_2::Face_const_handle      f;

    std::cout << "Shooting up from " << q << " : ";
    if (CGAL::assign (e, obj)) {
        // We hit an edge:
        std::cout << "hit an edge: " << e->curve() << std::endl;
    }
    else if (CGAL::assign (v, obj)) {
        // We hit a vertex:
        if (v->is_isolated())
            std::cout << "hit an isolated vertex: " << v->point() << std::endl;
        else
            std::cout << "hit a vertex: " << v->point() << std::endl;
    }
    else if (CGAL::assign (f, obj)) {
        // We did not hit anything:
        CGAL_assertion (f->is_unbounded());
    }
}
```

```

        std::cout << "hit nothing." << std::endl;
    }
    else {
        CGAL_assertion_msg (false, "Invalid object.");
    }
}

```

The following program uses the auxiliary function listed above to perform vertical ray-shooting queries on an arrangement. The arrangement and the query points are exactly the same as in *ex_point_location.C* (see Figure 17.7):

```

//! \file examples/Arrangement_2/ex_vertical_ray_shooting.C
// Answering vertical ray-shooting queries.

#include <CGAL/MP_Float.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_walk_along_line_point_location.h>
#include <CGAL/Arr_trapezoid_ric_point_location.h>

#include "point_location_utils.h"

typedef CGAL::MP_Float          Number_type;
typedef CGAL::Cartesian<Number_type> Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2      Point_2;
typedef CGAL::Arrangement_2<Traits_2> Arrangement_2;
typedef CGAL::Arr_walk_along_line_point_location<Arrangement_2> Walk_pl;
typedef CGAL::Arr_trapezoid_ric_point_location<Arrangement_2> Trap_pl;

int main ()
{
    // Construct the arrangement.
    Arrangement_2 arr;
    Walk_pl walk_pl (arr);
    Trap_pl trap_pl;

    construct_segments_arr (arr);

    // Perform some vertical ray-shooting queries using the walk strategy.
    Point_2 q1 (1, 4);
    Point_2 q2 (4, 3);
    Point_2 q3 (6, 3);

    vertical_ray_shooting_query (walk_pl, q1);
    vertical_ray_shooting_query (walk_pl, q2);
    vertical_ray_shooting_query (walk_pl, q3);

    // Attach the trapezoid-RIC object to the arrangement and perform queries.
    Point_2 q4 (3, 2);
    Point_2 q5 (5, 2);

```

```

Point_2          q6 (1, 0);

trap_pl.attach (arr);
vertical_ray_shooting_query (trap_pl, q4);
vertical_ray_shooting_query (trap_pl, q5);
vertical_ray_shooting_query (trap_pl, q6);

return (0);
}

```

The number type we use in this example is CGAL's built-in *MP_Float* type which is a floating-point number with an unbounded mantissa and a 32-bit exponent. It supports construction from an integer or from a machine *float* or *double* and performs additions, subtractions and multiplications in an exact number.

17.3.3 Batched Point-Location

Suppose that at a given moment our application has to issue a relatively large number m of point-location queries on a specific arrangement instance. It is possible of course to define a point-location object and to issue separate queries on the arrangement. However, as explained in Section 17.3.1, choosing a simple point-location strategy (either the naïve or the walk strategy) means inefficient queries, while the more sophisticated strategies need to construct auxiliary structures that incur considerable overhead in running time.

On the other hand, the arrangement package includes a free *locate()* function that accepts an arrangement a range of query points as its input and sweeps through the arrangement to locate all query points in one pass. The function outputs the query results as pairs, where each pair is comprised of a query point and a CGAL *Object* that represents the cell containing the point (see Section 17.3.1). The output pairs are sorted in increasing *xy*-lexicographical order of the query point.

The batched point-location operation can be performed in $O((m + N) \log(m + N))$ time, where N is the number of edges in the arrangement. This means that when the number m of point-location queries is of the same order of magnitude as N , this operation is more efficient than issuing separate queries. This suggestion is also backed up by experimental results. Moreover, the batched point-location operation is also advantageous as it does not have to construct and maintain additional data structures.

The following program issues a batched point-location query, which is essentially equivalent to the six separate queries performed in *ex_point_location.C* (see Section 17.3.1):

```

//! \file examples/Arrangement_2/ex_batched_point_location.C
// Answering a batched point-location query.

#include <CGAL/MP_Float.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_batched_point_location.h>
#include <list>

#include "point_location_utils.h"

typedef CGAL::MP_Float          Number_type;
typedef CGAL::Cartesian<Number_type> Kernel;

```

```

typedef CGAL::Arr_segment_traits_2<Kernel>           Traits_2;
typedef Traits_2::Point_2                           Point_2;
typedef CGAL::Arrangement_2<Traits_2>               Arrangement_2;
typedef std::pair<Point_2, CGAL::Object>             Query_result;

int main ()
{
    // Construct the arrangement.
    Arrangement_2    arr;

    construct_segments_arr (arr);

    // Perform a batched point-location query.
    std::list<Point_2>    query_points;
    std::list<Query_result> results;

    query_points.push_back (Point_2 (1, 4));
    query_points.push_back (Point_2 (4, 3));
    query_points.push_back (Point_2 (6, 3));
    query_points.push_back (Point_2 (3, 2));
    query_points.push_back (Point_2 (5, 2));
    query_points.push_back (Point_2 (1, 0));

    locate (arr, query_points.begin(), query_points.end(),
    std::back_inserter (results));

    // Print the results.
    std::list<Query_result>::const_iterator res_iter;
    Arrangement_2::Vertex_const_handle    v;
    Arrangement_2::Halfedge_const_handle  e;
    Arrangement_2::Face_const_handle      f;

    for (res_iter = results.begin(); res_iter != results.end(); ++res_iter)
    {
        std::cout << "The point (" << res_iter->first << ") is located ";
        if (CGAL::assign (f, res_iter->second))
        {
            // The current query point is located inside a face:
            if (f->is_unbounded())
                std::cout << "inside the unbounded face." << std::endl;
            else
                std::cout << "inside a bounded face." << std::endl;
        }
        else if (CGAL::assign (e, res_iter->second))
        {
            // The current query point is located on an edge:
            std::cout << "on an edge: " << e->curve() << std::endl;
        }
        else if (CGAL::assign (v, res_iter->second))
        {
            // The current query point is located on a vertex:
            if (v->is_isolated())
                std::cout << "on an isolated vertex: " << v->point() << std::endl;
            else

```

```

        std::cout << "on a vertex: " << v->point() << std::endl;
    }
}

return (0);
}

```

17.4 Free Functions in the Arrangement Package

In Section 17.2 we reviewed in details the *Arrangement_2* class, which represents two-dimensional subdivisions induced by bounded planar curves, and mentioned that its interface is minimal in the sense that the member functions hardly perform any geometric algorithms and are mainly used for maintaining the topological structure of the subdivision. In this section we explain how to utilize the free (global) functions that operate on arrangements. The implementation of these operations typically require non-trivial geometric algorithms or load some extra requirements on the traits class.

17.4.1 Incremental Insertion Functions

Inserting Non-Intersecting Curves

In Section 17.2 we explained how to construct arrangements of x -monotone curves that are pairwise disjoint in their interior, when the location of the segment endpoints in the arrangement is known. Here we relax this constraint, and allow the location of the inserted x -monotone curve endpoints to be arbitrary, as it may be unknown at the time of insertion. We retain, for the moment, the requirement that the interior of the inserted curve is disjoint from all existing arrangement edges and vertices.

The free function *insert_non_intersecting_curve*(*arr*, *c*, *pl*) inserts the x -monotone curve *c* into the arrangement *arr*, with the precondition that the interior of *c* is disjoint from all *arr*'s existing edges and vertices. The third argument *pl* is a point-location object attached to the arrangement, which is used for performing the insertion. It locates both curve endpoints in the arrangement, where each endpoint is expected to either coincide with an existing vertex or lie inside a face. It is possible to invoke one of the specialized insertion functions (see Section 17.2), based on the query results, and insert *c* at its proper position.⁸ The insertion operation thus hardly requires any geometric operations on top on the ones needed to answer the point-location queries. Moreover, it is sufficient that the arrangement class is instantiated with a traits class that models the *ArrangementBasicTraits_2* concept (or the *ArrangementLandmarkTraits_2* concept, if the landmark point-location strategy is used), which does not have to support the computation of intersection points between curves.

The variant *insert_non_intersecting_curve*(*arr*, *c*) is also available. Instead of accepting a user-defined point-location object, it defines a local instance of the walk point-location class and uses it to insert the curve.

Inserting x -Monotone Curves

The *insert_non_intersecting_curve*() function is very efficient, but its preconditions on the input curves are still rather restricting. Let us assume that the arrangement is instantiated with a traits class that models the refined *ArrangementXMonotoneTraits_2* concept and supports intersection computations (see Section 17.5 for the exact

⁸The *insert_non_intersecting_curve*() function, as all other functions reviewed in this section, is a function template, parameterized by an arrangement class and a point-location class (a model of the *ArrangementPointLocation_2* concept).

details). Given an x -monotone curve, it is sufficient to locate its left endpoint in the arrangement and to trace its *zone*, namely the set of arrangement features crossing the curve, until the right endpoint is reached. Each time the new curve c crosses an existing vertex or an edge, the curve is split into subcurves (in the latter case, we have to split the curve associated with the existing halfedge as well) and associate new edges with the resulting subcurves. Recall that an edge is represented by a pair of twin halfedges, so we split it into two halfedge pairs.

The free function `insert_x_monotone_curve(arr, c, pl)` performs this insertion operation. It accepts an x -monotone curve c , which may intersect some of the curves already in the arrangement arr , and inserts it into the arrangement by computing its zone. Users may supply a point-location object pl , or use the default walk point-location strategy (namely, the variant `insert_x_monotone_curve(arr, c)` is also available). The running-time of this insertion function is proportional to the complexity of the zone of the curve c .

— advanced —

In some cases users may have a prior knowledge of the location of the left endpoint of the x -monotone curve c they wish to insert, so they can perform the insertion without issuing any point-location queries. This can be done by calling `insert_x_monotone_curve(arr, c, obj)`, where obj is an object represents the location of c 's left endpoint in the arrangement — namely it wraps a `Vertex_const_handle`, a `Halfedge_const_handle` or a `Face_const_handle` (see also Section 17.3.1).

— advanced —

Inserting General Curves

So far all our examples were of arrangements of line segments, where the `Arrangement_2` template was instantiated with the `Arr_segment_traits_2` class. In this case, the fact that `insert_x_monotone_curve()` accepts an x -monotone curve does not seem to be a restriction, as all line segments are x -monotone (note that we consider vertical line segments to be *weakly* x -monotone).

Suppose that we construct an arrangement of circles. A circle is obviously not x -monotone, so we cannot use `insert_x_monotone_curve()` in this case.⁹ However, it is possible to subdivide each circle into two x -monotone circular arcs (its upper half and its lower half) and to insert each x -monotone arc separately.

The free function `insert_curve()` requires that the traits class used by the arrangement arr to be a model of the concept `ArrangementTraits_2`, which refines the `ArrangementXMonotoneTraits_2` concept. It has to define an additional `Curve_2` type (which may differ from the `X_monotone_curve_2` type), and support the subdivision of curves of this new type into x -monotone curves (see the exact details in Section 17.5). The `insert_curve(arr, c, pl)` function performs the insertion of the curve c , which does not need to be x -monotone, into the arrangement by subdividing it into x -monotone subcurves and inserting each one separately. Users may supply a point-location object pl , or use the default walk point-location strategy by calling `insert_curve(arr, c)`.

Inserting Points

The arrangement class enables us to insert a point as an isolated vertex in a given face. The free function `insert_point(arr, p, pl)` inserts a vertex into arr that corresponds to the point p at an arbitrary location. It uses the point-location object pl to locate the point in the arrangement (by default, the walk point-location strategy is used), and acts according to the result as follows:

- If p is located inside a face, it is inserted as an isolated vertex inside this face.

⁹Note that a key operation performed by `insert_x_monotone_curve()` is to locate the left endpoint of the curve in the arrangement. A circle, however, does not have any endpoints!

Figure 17.8: An arrangement of five intersecting line segments, as constructed in *ex_incremental_insertion.C* and *ex_aggregated_insertion.C*. The segment endpoints are marked by black disks and the arrangement vertices that correspond to intersection points are marked by circles. The query point q is marked with a cross and the face that contains it is shaded.

- If p lies on an edge, the edge is split to create a vertex associated with p .
- Otherwise, p coincides with an existing vertex and we are done.

In all cases, the function returns a handle to the vertex associated with p .

The arrangement *arr* should be instantiated with a traits class that models the *ArrangementXMonotoneTraits_2* concept, as the insertion operation may involve splitting curves.

An Example

The program below constructs an arrangement of intersecting line-segments. We know that s_1 and s_2 do not intersect, so we use *insert_non_intersecting_curve()* to insert them into the empty arrangement. The rest of the segments are inserted using *insert_x_monotone_curve()* or *insert_curve()*, which are equivalent in case of line segments. The resulting arrangement consists of 13 vertices, 16 edges, and 5 faces, as can be seen in Figure 17.8.

In the earlier examples, all arrangement vertices corresponded to segment endpoints. In this example we have additional vertices that correspond to intersection points between two segments. The coordinates of these intersection points are rational numbers, if the input coordinates are rational (or integer). Therefore, the *Quotient<int>* number type is used to represent the coordinates:

```

//! \file examples/Arrangement_2/ex_incremental_insertion.C
// Using the global incremental insertion functions.

#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_walk_along_line_point_location.h>

#include "arr_print.h"

```

```

typedef CGAL::Quotient<int>                               Number_type;
typedef CGAL::Cartesian<Number_type>                      Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                Traits_2;
typedef Traits_2::Point_2                                 Point_2;
typedef Traits_2::X_monotone_curve_2                     Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                     Arrangement_2;
typedef CGAL::Arr_walk_along_line_point_location<Arrangement_2> Walk_pl;

int main ()
{
    // Construct the arrangement of five intersecting segments.
    Arrangement_2 arr;
    Walk_pl      pl(arr);

    Segment_2     s1 (Point_2(1, 0), Point_2(2, 4));
    Segment_2     s2 (Point_2(5, 0), Point_2(5, 5));
    Segment_2     s3 (Point_2(1, 0), Point_2(5, 3));
    Segment_2     s4 (Point_2(0, 2), Point_2(6, 0));
    Segment_2     s5 (Point_2(3, 0), Point_2(5, 5));

    insert_non_intersecting_curve (arr, s1, pl);
    insert_non_intersecting_curve (arr, s2, pl);
    insert_x_monotone_curve (arr, s3, pl);
    insert_x_monotone_curve (arr, s4, pl);
    insert_curve (arr, s5, pl);

    // Print the size of the arrangement.
    std::cout << "The arrangement size:" << std::endl
              << "    V = " << arr.number_of_vertices()
              << ",    E = " << arr.number_of_edges()
              << ",    F = " << arr.number_of_faces() << std::endl;

    // Perform a point-location query on the resulting arrangement and print
    // the boundary of the face that contains it.
    Point_2      q (4, 1);
    CGAL::Object  obj = pl.locate (q);

    Arrangement_2::Face_const_handle f;
    bool          success = CGAL::assign (f, obj);

    CGAL_assertion (success);
    std::cout << "The query point (" << q << ") is located in: ";
    print_face<Arrangement_2> (f);

    return (0);
}

```

17.4.2 Aggregated Insertion Functions

Let us assume that we have to insert a set of m input curves into an arrangement. It is possible to do this incrementally, inserting the curves one by one, as shown in the previous section. However, the arrangement

package provides three free functions that aggregately insert a range of curves into an arrangement:

- *insert_non_intersecting_curves(arr, begin, end)* inserts a range of x -monotone curves given by the input iterators $[begin, end)$ into an arrangement *arr*. The x -monotone curves should be pairwise disjoint in their interior and also interior-disjoint from all existing edges and vertices of *arr*.
- *insert_x_monotone_curves(arr, begin, end)* operates on a range of x -monotone curves that may intersect one another.
- *insert_curves(arr, begin, end)* inserts a range of of general (not necessarily x -monotone) curves of type *Curve_2*, given by the input iterators $[begin, end)$, into the arrangement *arr*.

We distinguish between two cases: (i) The given arrangement *arr* is empty (has only an unbounded face), so we have to construct it from scratch. (ii) We have to insert m input curves to a non-empty arrangement *arr*.

In the first case, we sweep over the input curves, compute their intersection points and construct the DCEL that represents their planar arrangement. This process is performed in $O((m+k)\log m)$ time, where k is the total number of intersection points. The running time is asymptotically better than the time needed for incremental insertion, if the arrangement is relatively sparse (when k is bounded by $\frac{m^2}{\log m}$), but in practice it is recommended to use this aggregated construction process even for dense arrangements, since the sweep-line algorithm needs less geometric operations compared to the incremental insertion algorithms and hence typically runs much faster in practice.

Another important advantage the aggregated insertion functions have is that they do not issue point-location queries. Thus, no point-location object needs to be attached to the arrangement. As explained in Section 17.3.1, there is a trade-off between construction time and query time in each of the point-location strategies, which affects the running times of the incremental insertion process. Naturally, this trade-off is irrelevant in case of aggregated insertion as above.

The example below shows how to construct the arrangement of line segments depicted in Figure 17.8 and built incrementally in *ex_incremental_insertion.C*, as shown in the previous section. We use the aggregated insertion function *insert_x_monotone_curves()* as we deal with line segments. Note that no point-location object needs to be defined and attached to the arrangement:

```

//! \file examples/Arrangement_2/ex_aggregated_insertion.C
// Using the global aggregated insertion functions.

#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <list>

typedef CGAL::Quotient<int>           Number_type;
typedef CGAL::Cartesian<Number_type> Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2            Point_2;
typedef Traits_2::X_monotone_curve_2 Segment_2;
typedef CGAL::Arrangement_2<Traits_2> Arrangement_2;

int main ()
{
    // Construct the arrangement of five intersecting segments.
    Arrangement_2 arr;

```

Figure 17.9: An arrangement of intersecting line segments, as constructed in *ex_global_insertion.C*. The segments of \mathcal{S}_1 are drawn in solid lines and the segments of \mathcal{S}_2 are drawn in dark dashed lines. Note that the segment s (light dashed line) overlaps one of the segments in \mathcal{S}_1 .

```
std::list<Segment_2>    segments;;

segments.push_back (Segment_2 (Point_2(1, 0), Point_2(2, 4)));
segments.push_back (Segment_2 (Point_2(5, 0), Point_2(5, 5)));
segments.push_back (Segment_2 (Point_2(1, 0), Point_2(5, 3)));
segments.push_back (Segment_2 (Point_2(0, 2), Point_2(6, 0)));
segments.push_back (Segment_2 (Point_2(3, 0), Point_2(5, 5)));

insert_x_monotone_curves (arr, segments.begin(), segments.end());

// Print the size of the arrangement.
std::cout << "The arrangement size:" << std::endl
    << "    V = " << arr.number_of_vertices()
    << ",    E = " << arr.number_of_edges()
    << ",    F = " << arr.number_of_faces() << std::endl;

return (0);
}
```

In case we have to insert a set of m curves into an existing arrangement, where we denote the number of edges in the arrangement by N . As a rule of thumb, if $m = o(\sqrt{N})$, we insert the curves one by one. For larger input sets, we use the aggregated insertion procedures.

In the example below we aggregately construct an arrangement of a set \mathcal{S}_1 containing five line segments. Then we insert a single segment using the incremental insertion function. Finally, we add a set \mathcal{S}_2 with five more line segments in an aggregated fashion. Notice that the line segments of \mathcal{S}_1 are pairwise interior-disjoint, so we use *insert_non_intersecting_curves()*. \mathcal{S}_2 also contain pairwise interior-disjoint segments, but as they intersect the existing arrangement, we have to use *insert_x_monotone_curves()* to insert them. Also note that the single segment s we insert incrementally overlaps an existing arrangement edge:

```
/// \file examples/Arrangement_2/ex_global_insertion.C
// Using the global insertion functions (incremental and aggregated).
```

```

#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

#include "arr_print.h"

typedef CGAL::Quotient<CGAL::MP_Float>          Number_type;
typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;

int main ()
{
    // Construct the arrangement of five intersecting segments.
    Arrangement_2    arr;
    Segment_2        S1 [5];

    S1[0] = Segment_2 (Point_2 (1, 2.5), Point_2 (4, 5));
    S1[1] = Segment_2 (Point_2 (1, 2.5), Point_2 (6, 2.5));
    S1[2] = Segment_2 (Point_2 (1, 2.5), Point_2 (4, 0));
    S1[3] = Segment_2 (Point_2 (4, 5), Point_2 (6, 2.5));
    S1[4] = Segment_2 (Point_2 (4, 0), Point_2 (6, 2.5));

    insert_non_intersecting_curves (arr, S1, S1 + 5);

    // Perform an incremental insertion of a single overlapping segment.
    Naive_pl          pl (arr);

    insert_x_monotone_curve (arr,
                             Segment_2 (Point_2 (0, 2.5), Point_2 (4, 2.5)),
                             pl);

    // Aggregately insert an additional set of five segments.
    Segment_2        S2 [5];

    S2[0] = Segment_2 (Point_2 (0, 4), Point_2 (6, 5));
    S2[1] = Segment_2 (Point_2 (0, 3), Point_2 (6, 4));
    S2[2] = Segment_2 (Point_2 (0, 2), Point_2 (6, 1));
    S2[3] = Segment_2 (Point_2 (0, 1), Point_2 (6, 0));
    S2[4] = Segment_2 (Point_2 (6, 1), Point_2 (6, 4));

    insert_x_monotone_curves (arr, S2, S2 + 5);

    // Print the size of the arrangement.
    std::cout << "The arrangement size:" << std::endl
               << "    V = " << arr.number_of_vertices()
               << ",    E = " << arr.number_of_edges()

```

```

    << ", F = " << arr.number_of_faces() << std::endl;

    return (0);
}

```

The number type used in the example above, *Quotient<MP_Float>*, is comprised of a numerator and a denominator of type *MP_Float*, namely floating-point numbers with unbounded mantissa. This number type is therefore capable of exactly computing the intersection points as long as the segment endpoints are given as floating-point numbers.

17.4.3 Removing Vertices and Edges

The free functions *remove_vertex()* and *remove_edge()* handle the removal of vertices and edges from an arrangement. The difference between these functions and the member functions of the *Arrangement_2* template having the same name is that they allow the merger of two curves associated with adjacent edges to form a single edge. Thus, they require that the traits class that instantiates the arrangement instance is a model of the refined *ArrangementXMonotoneTraits_2* concept (see Section 17.5).

The function *remove_vertex(arr, v)* removes the vertex *v* from the given arrangement *arr*, where *v* is either an isolated vertex or is a *redundant* vertex — namely, it has exactly two incident edges that are associated with two curves that can be merged to form a single *x*-monotone curve. If neither of the two cases apply, the function returns an indication that it has failed to remove the vertex.

The function *remove_edge(arr, e)* removes the edge *e* from the arrangement by simply calling *arr.remove_edge(e)* (see Section 17.2.3). In addition, if either of the end vertices of *e* becomes isolated or redundant after the removal of the edge, it is removed as well.

The following example demonstrates the usage of the free removal functions. It creates an arrangement of four line segment forming an H-shape with a double horizontal line. Then it removes the two horizontal edges and clears all redundant vertices, such that the final arrangement consists of just two edges associated with the vertical line segments:

```

//! \file examples/Arrangement_2/ex_global_removal.C
// Using the global removal functions.

#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

#include "arr_print.h"

typedef int
typedef CGAL::Cartesian<Number_type>
typedef CGAL::Arr_segment_traits_2<Kernel>
typedef Traits_2::Point_2
typedef Traits_2::X_monotone_curve_2
typedef CGAL::Arrangement_2<Traits_2>
typedef Arrangement_2::Vertex_handle

Number_type;
Kernel;
Traits_2;
Point_2;
Segment_2;
Arrangement_2;
Vertex_handle;

```

```

typedef Arrangement_2::Halfedge_handle      Halfedge_handle;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;

int main ()
{
    // Create an arrangement of four line segments forming an H-shape.
    Arrangement_2  arr;
    Naive_pl       pl (arr);

    Segment_2      s1 (Point_2 (1, 3), Point_2 (4, 3));
    Halfedge_handle e1 = arr.insert_in_face_interior (s1, arr.unbounded_face());
    Segment_2      s2 (Point_2 (1, 4), Point_2 (4, 4));
    Halfedge_handle e2 = arr.insert_in_face_interior (s2, arr.unbounded_face());
    Segment_2      s3 (Point_2 (1, 1), Point_2 (1, 6));
    Segment_2      s4 (Point_2 (4, 1), Point_2 (4, 6));

    insert_curve (arr, s3, pl);
    insert_curve (arr, s4, pl);

    std::cout << "The initial arrangement:" << std::endl;
    print_arrangement (arr);

    // Remove the horizontal edge e1 from the arrangement using the member
    // function remove_edge(), then remove its end vertices.
    Vertex_handle  v1 = e1->source(), v2 = e1->target();

    arr.remove_edge (e1);
    remove_vertex (arr, v1);
    remove_vertex (arr, v2);

    // Remove the second horizontal edge e2 from the arrangement using the
    // free remove_edge() function.
    remove_edge (arr, e2);

    std::cout << "The final arrangement:" << std::endl;
    print_arrangement (arr);
    return (0);
}

```

17.5 Traits Classes

As mentioned in the introduction of this chapter, the traits class encapsulates the definitions of the geometric entities and implements the geometric predicates and constructions needed by the *Arrangement_2* class and by its peripheral algorithms. We also mention throughout the chapter that there are different levels of requirements from the traits class, namely the traits class can model different concept refinement-levels.

A model of the basic concept, *ArrangementBasicTraits_2*, needs to define the types *Point_2* and *X_monotone_curve_2*, where objects of the first type are the geometric mapping of arrangement vertices, and objects of the latter type are the geometric mapping of edges. In addition, it has to support the following set of predicates:

- Compare the x -coordinates of two points p and q .

- Compare two points p and q lexicographically, by their x -coordinates then by their y -coordinates.
- Return the left endpoint (similarly, the right endpoint) of an x -monotone curve c .
- Given an x -monotone curve c and a point p that lies in its x -range, determine whether p lies below, above or on c .
- Given two x -monotone curves c_1 and c_2 that share a common left endpoint (similarly, right endpoint) p , determine whether c_1 lies above or under c_2 immediately to the right (to the left) of p , or whether the two curves coincide there.
- Check two curves for equality (two curves are equal if their graph is the same).

This basic set of predicates is sufficient for constructing arrangements of x -monotone curves and points that are pairwise disjoint in their interiors and for performing point-location queries and vertical ray-shooting queries.

The landmark point-location strategy (see Section 17.3.1) needs its associated arrangement to be instantiated with a model of the refined *ArrangementLandmarkTraits_2* traits concept. A model of this concept must define a fixed precision number type (typically *double*) and support the additional operations:

- Given a point p , approximate the x and y -coordinates of p using the fixed precision number type. We use this operation for approximate computations — there are certain operations in the search for the location of the point that need not be exact and we can perform them faster than other operations.
- Given two points p_1 and p_2 , construct an x -monotone curve connecting p_1 and p_2 .

A traits class that models the *ArrangementXMonotoneTraits_2* concept, which refines the *ArrangementBasicTraits_2* concept, has to support the following functions:

- Compute all intersection points and overlapping sections of two given x -monotone curves. If possible, compute also the multiplicity of each intersection point.¹⁰ Knowing the multiplicity of an intersection point is not required, but it can speed up the arrangement construction.
- Split an x -monotone curve c into two subcurves at a point p lying in the interior of c .
- Given two x -monotone curve c_1 and c_2 that share a common endpoint, determine whether c_1 and c_2 are *mergeable*, that is, whether they can be merged to form a single continuous x -monotone curve of the type supported by the traits class.
- Merge two mergeable x -monotone curve c_1 and c_2 .

Using a model of the *ArrangementXMonotoneTraits_2*, it is possible to construct arrangements of sets of x -monotone curves (and points) that may intersect one another.

The concept *ArrangementTraits_2* refines the *ArrangementXMonotoneTraits_2* concept by adding the notion of a general, not necessarily x -monotone (and not necessarily connected) curve. A model of this concept must define the *Curve_2* type and support the division of a curve into a set of continuous x -monotone curves and isolated points. For example, the curve $C : (x^2 + y^2)(x^2 + y^2 - 1) = 0$ is the unit circle (the loci of all points for which $x^2 + y^2 = 1$) with the origin $(0,0)$ as a singular point in its interior. C should therefore be divided into two circular arcs (the upper part and the lower part of the unit circle) and a single isolated point.

Note that the refined model *ArrangementTraits_2* is required only when using the free *insert_curve()* and *insert_curves()* functions (see Section 17.4), which accept a *Curve_2* object in the incremental version, or a

¹⁰If the two curves intersect at a point p but have different tangents, p is of multiplicity 1. If the tangents are also equal but the their curvatures are not the same, p is of multiplicity 2, etc.

range of *Curve_2* objects in the aggregated version. In all other cases it is sufficient to use a model of the *ArrangementXMonotoneTraits_2* concept.

In the rest of this section we review the traits classes included in the public distribution of CGAL, that handle line segments, polylines and conic arcs. The last subsection overviews decorators for geometric traits classes distributed with CGAL, which extend other geometric traits-class by attaching auxiliary data with the geometric objects.

17.5.1 Traits Classes for Line Segments

The *Arr_segment_traits_2*<*Kernel*> class used so far in all example programs in this chapter is parameterized by a geometric kernel and uses the *Kernel::Point_2* type as its point type. However, neither the *Curve_2* nor the *X_monotone_curve_2* types are identical to the *Kernel::Segment_2* type. A kernel segment is typically represented by its two endpoints, and these may have a large bit-size representation, if the segment is intersected and split several times (in comparison with the representation of its original endpoints). The large representation may significantly slow down the various traits-class operations involving such a segment. In contrast, the *Arr_segment_traits_2* represents a segment using its supporting line and the two endpoints, such that most computations are performed on the supporting line, which never changes as the segment is split. It also caches some additional information with the segment to speed up various predicates. An *X_monotone_curve_2* object can still be constructed from two endpoints or from a kernel segment. Moreover, an *X_monotone_curve_2* instance can also be casted or assigned to a *Kernel::Segment_2* object. The two types are thus fully convertible to one another.

The *Arr_segment_traits_2*<*Kernel*> class is very efficient for maintaining arrangements of a large number of intersecting line segments, especially if it is instantiated with the appropriate geometric kernel. Using *Cartesian*<*Gmpq*> as the kernel type is generally a good choice; the coordinates of the segment endpoints are represented as exact rational numbers, and this ensures the robustness and correctness of any computation. However, if the GMP library is not installed, it is possible to use the *Quotient*<*MP_Float*> number-type, provided by the support library of CGAL, which is somewhat less efficient.¹¹

Exact computations are of course less efficient, compared to machine-precision floating-point arithmetic, so constructing an arrangement using the *Cartesian*<*Gmpq*> kernel (or, similarly, *Cartesian*<*Quotient*<*MP_Float*>>) is several times slower in comparison to a *Simple_cartesian*<*double*> kernel. However, in the latter case the correctness of the computation results is not guaranteed. In many cases it is possible to use *filtered* computations and benefit from both approaches, namely achieve fast running times with guaranteed results. In case we handle a set of line segments that have no degeneracies, namely no two segments share a common endpoint, and no three segments intersect at a common point — or alternatively, degeneracies exist but their number is relatively small — then filtered computation incur only a minor overhead compared to the floating-point arithmetic, while ensuring the correctness of the computation results.

In the following example we use the predefined *Exact_predicates_exact_constructions_kernel* for instantiating our segment-traits class. This kernel uses interval arithmetic to filter the exact computations. The program reads a set of line segments with integer coordinates from a file and computes their arrangement. By default it opens the *fan_grids.dat* input-file, located in the examples folder, which contains 104 line segments that form four “fan-like” grids and induce a dense arrangement, as illustrated in Figure 17.10(a):

```

//! \file examples/Arrangement_2/ex_predefined_kernel.C
// Constructing an arrangements of intersecting line segments using the
// predefined kernel with exact constructions and exact predicates.

```

¹¹Many of the example programs in the rest of the chapter include a header file named *arr_rational_nt.h*, which defines a type named *Number_type* as either *Gmpq* or *Quotient*<*MP_Float*>, depending on whether GMP is installed or not.

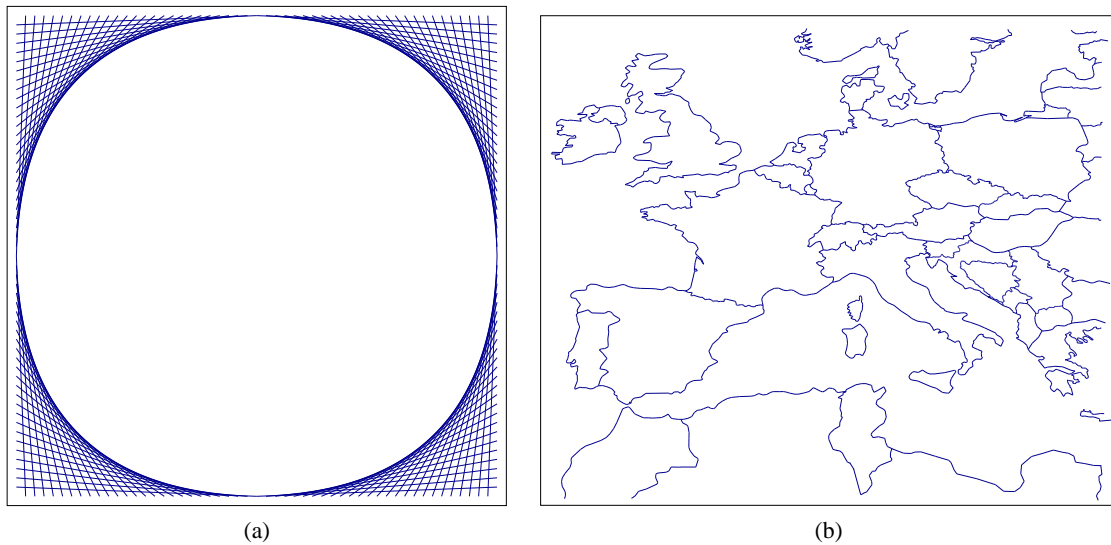

Figure 17.10: (a) An arrangement of 104 line segments from the input file *fan_grids.dat*. (b) An arrangement of more than 3000 interior disjoint line segments, defined in the input file *Europe.dat*.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Arr_segment_traits_2.h>

std::cout << "Construction took " << timer.time()
           << " seconds." << std::endl;

return 0;
}

```

The arrangement package also offers a simpler alternative segment-traits class. The traits class *Arr_non_caching_segment_basic_traits_2<Kernel>* models the *ArrangementBasicTraits_2* concept. It uses *Kernel::Point_2* as its point type and *Kernel::Segment_2* as its *x*-monotone curve type. As this traits class does not support intersecting and splitting segments, the kernel representation is sufficient. It is still less efficient than *Arr_segment_traits_2* for constructing arrangements of pairwise disjoint line segments in many cases, as it performs no caching at all, but using this traits class may be preferable as it reduces the memory consumption a bit, since no extra data is stored with the line segments.

The class *Arr_non_caching_segment_traits_2<Kernel>* inherits from *Arr_non_caching_segment_basic_traits_2<Kernel>* and extends it to be a model of the *ArrangementTraits_2* concept. It may thus be used to construct arrangement of intersecting line segments, but as explained above, for efficiency reasons it is recommended to use it only when the arrangement is very sparse and contains hardly any intersection points.

In the following example we read an input file containing a set of line segments that are pairwise disjoint in their interior. As the segments do not intersect, no new points are constructed and we can instantiate the *Arr_non_caching_segment_traits_basic_2<Kernel>* class-template with the predefined *Exact_predicates_inexact_constructions_kernel*. Note that we use the *insert_non_intersecting_curves()* function to construct the arrangement. By default, the example opens the *Europe.dat* input-file, located in the examples folder, which contains more than 3000 line segments with floating-point coordinates that form the map of Europe, as depicted in Figure 17.10(b):

```

//! \file examples/Arrangement_2/ex_predefined_kernel_non_intersecting.C
// Constructing an arrangement of non-intersecting line segments using the
// predefined kernel with exact predicates.

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Arr_non_caching_segment_basic_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Timer.h>
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel   Kernel;
typedef Kernel::FT                                             Number_type;
typedef CGAL::Arr_non_caching_segment_basic_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2                                     Point_2;
typedef Traits_2::X_monotone_curve_2                          Segment_2;

           << ", E = " << arr.number_of_edges()
           << ", F = " << arr.number_of_faces() << std::endl;

std::cout << "Construction took " << timer.time()
           << " seconds." << std::endl;

return 0;
}

```

17.5.2 The Polyline-Traits Class

The *Arr_polyline_traits_2*<*SegmentTraits*> class can be used to maintain arrangements of polylines (a.k.a. poly-segments), which are continuous piecewise linear curves. A polyline can be created from a range of points, where the i -th and $(i+1)$ -st points in the range represent the endpoints of the i -th segment of the polyline. The polyline traits class is parameterized with a segment-traits class that supports the basic operations on segments.

Polylines are the simplest form of a curves that are not necessarily x -monotone. They can be used to approximate more complicated curves in a convenient manner, as the algebra needed to handle them is elementary — rational arithmetic is sufficient to construct an arrangement of polylines in an exact and robust manner. Note, however,

Figure 17.11: An arrangement of three polylines, as constructed in *ex_polylines.C*. Disks mark vertices associated with polyline endpoints, while circles mark vertices that correspond to intersection points. Note that π_2 is split into three x -monotone polylines, and that π_1 and π_3 have two overlapping sections.

that a single polyline can be split into many x -monotone polylines, and that the number of intersection points (or overlapping sections) between two polylines can also be large.

The `polyline-traits` class is a model of the *ArrangementTraits_2* concept and of the *ArrangementLandmarkTraits_2* concept. It inherits its point type from the `segment-traits` class, and defines the `polyline` type, which serves as its *Curve_2*. Polyline curve objects can be constructed from a range of points. They also enable the traversal over the range of defining points, whose first and past-the-end iterators can be obtained through the methods *begin()* and *end()*. The nested *X_monotone_curve_2* type inherits from *Curve_2*. The points in an x -monotone curve are always stored in lexicographically increasing order of their coordinates.

The following example program constructs an arrangement of three polylines, as depicted in Figure 17.11. Note that most points defining the polylines are not associated with arrangement vertices. The arrangement vertices are either the extreme points of each x -monotone polyline or the intersection points between two polylines:

```

//! \file examples/Arrangement_2/ex_polylines.C
// Constructing an arrangement of polylines.

#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>

    points3[2] = Point_2 (3, 6);
    points3[3] = Point_2 (5, 2);
    Polyline_2 pi3 (points3.begin(), points3.end());

    insert_curve (arr, pi1);
    insert_curve (arr, pi2);
    insert_curve (arr, pi3);

    print_arrangement (arr);
    return 0;
}

```

17.5.3 A Traits Class for Circular Arcs and Line Segments

Circles and circular arcs are the simplest form of non-linear curves. We handle circles whose centers have rational coordinates and whose squared radii is also rational. If we denote the circle center by (x_0, y_0) and its radius by r , then the equation of the circle — that is, $(x - x_0)^2 + (y - y_0)^2 = r^2$ — has rational coefficients. The intersection points of two such circles are therefore solutions of a quadratic equation with rational coefficients, or algebraic numbers of degree 2. The same applies for intersection points between such a rational circle and a line, or a line segment, with rational coefficients (a line whose equation is $ax + by + c = 0$, where a , b and c are

Figure 17.12: An arrangement of three circles constructed in *ex_circles.C*. Each circle is split into two x -monotone circular arcs, whose endpoints are drawn as disks. Circles mark vertices that correspond to intersection points. The vertex v_{\max} is a common intersection point of all three circles.

rational). Such numbers can be expressed as $\alpha + \beta\sqrt{\gamma}$, where α , β and γ are all rational numbers.

Arrangement of circular arcs and of line segment are very useful, as they occur in many applications. For example, when dilating a polygon by some radius we obtain a shape whose boundary is comprised of line segments, which correspond to dilated polygon edges, and circular arcs, which result from dilated polygon vertices. Using the arrangement of the boundary curves it is possible, for example, to compute the union of a set of dilated polygons.

The *Arr_circle_segment_traits_2*<*Kernel*> class-template is designed for efficient handling of arrangements of circular arcs and line segments. It is parameterized by a geometric kernel, and can handle arrangements of segments of *Kernel::Circle_2* objects (full circles are also supported) or of *Kernel::Line_2* objects — namely circular arcs and line segments. It is important to observe that the nested *Point_2* type defined by the traits class, whose coordinates are typically algebraic numbers of degree 2, is *not* the same as the *Kernel::Point_2* type, which is capable of representing a point with rational coordinates. The coordinates of a point are represented using the nested *CoordNT* number-type.

In the following example an arrangement of three full circles is constructed, as shown in Figure 17.12. Then, the vertex of maximal degree is searched for. The geometric mapping of this vertex is the point (4,3), as all three circles intersect at this point and the associated vertex has six incident edges:

```

//! \file examples/Arrangement_2/ex_circles.C
// Constructing an arrangement of circles using the conic-arc traits.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>          Kernel;
typedef Kernel::Circle_2                      Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::CoordNT                    CoordNT;
typedef Traits_2::Point_2                    Point_2;
typedef Traits_2::Curve_2                    Curve_2;

```

```

typedef CGAL::Arrangement_2<Traits_2> Arrangement_2;

int main ()
{
    // Create a circle centered at the origin with radius 5.
    Kernel::Point_2 c1 = Kernel::Point_2 (0, 0);
    Number_type      sqr_r1 = Number_type (25);      // = 5^2
    Circle_2         circ1 = Circle_2 (c1, sqr_r1, CGAL::CLOCKWISE);
    Curve_2          cv1 = Curve_2 (circ1);

    // Create a circle centered at (7,7) with radius 5.
    Kernel::Point_2 c2 = Kernel::Point_2 (7, 7);
    Number_type      sqr_r2 = Number_type (25);      // = 5^2
    Circle_2         circ2 = Circle_2 (c2, sqr_r2, CGAL::CLOCKWISE);
    Curve_2          cv2 = Curve_2 (circ2);

    // Create a circle centered at (4,-0.5) with radius 3.5 (= 7/2).
    Kernel::Point_2 c3 = Kernel::Point_2 (4, Number_type (-1,2));
    Number_type      sqr_r3 = Number_type (49, 4);   // = 3.5^2
    Circle_2         circ3 = Circle_2 (c3, sqr_r3, CGAL::CLOCKWISE);
    Curve_2          cv3 = Curve_2 (circ3);

    // Construct the arrangement of the three circles.
    Arrangement_2    arr;

    insert_curve (arr, cv1);
    insert_curve (arr, cv2);
    insert_curve (arr, cv3);

    // Locate the vertex with maximal degree.
    Arrangement_2::Vertex_const_iterator vit;
    Arrangement_2::Vertex_const_handle   v_max;
    unsigned int                         max_degree = 0;

    for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit)
    {
        if (vit->degree() > max_degree)
        {
            v_max = vit;
            max_degree = vit->degree();
        }
    }

    std::cout << "The vertex with maximal degree in the arrangement is: "
               << "v_max = (" << v_max->point() << ") "
               << "with degree " << max_degree << "." << std::endl;

    return (0);
}

```

The *Curve_2* type nested in *Arr_circle_segment_traits_2* can be used to represent circles, circular arcs, or line segments. Curve objects can therefore be constructed from a *Kernel::Circle_2* object or from a *Kernel::Segment_2* object. A circular arc is typically defined by a supporting circle and two endpoints, where

the endpoints are instances of the *Point_2* type, with rational or irrational coordinates. The orientation of the arc is determined by the orientation of the supporting circle. Similarly, we also support the construction of lines segments given their supporting line (of type *Kernel::Line_2*) and two endpoints, which may have irrational coordinates (unlike the *Kernel::Segment_2* type).

Note that the *Kernel::Circle_2* type represents a circle whose *squared radius* is rational, where the radius itself may be irrational. However, if the radius is known to be rational, it is advisable to use it, for efficiency reasons. It is therefore also possible to construct a circle, or a circular arc specifying the circle center (a *Kernel::Point_2*), its rational radius, and its orientation. Finally, we also support the construction of a circular arcs that is defined by two endpoints and an arbitrary midpoint that lies on the arc in between its endpoint. In this case, all three points are required to have rational coordinates (to be kernel points).

The following example demonstrates the usage of the various construction methods for circular arcs and line segments. Note the usage of the constructor of *CoordNT* (*alpha*, *beta*, *gamma*), which creates a degree-2 algebraic number whose value is $\alpha + \beta\sqrt{\gamma}$.

```

//! \file examples/Arrangement_2/ex_circular_arc.C
// Constructing an arrangement of various circular arcs and line segments.

curves.push_back (Curve_2 (s7, mid7, t7));

// Construct the arrangement of the curves.
Arrangement_2 arr;

insert_curves (arr, curves.begin(), curves.end());

// Print the size of the arrangement.
std::cout << "The arrangement size:" << std::endl
    << "    V = " << arr.number_of_vertices()
    << ",    E = " << arr.number_of_edges()
    << ",    F = " << arr.number_of_faces() << std::endl;

return (0);

```

}

It is also possible to construct x -monotone curve objects, which represent x -monotone circular arcs or line segments, using similar constructors. Construction from a full circle is obviously not supported. See the Reference Manual for more details.

17.5.4 A Traits Class for Conic Arcs

A *conic curve* is an algebraic curve of degree 2. Namely, it is the locus of all points (x, y) satisfying the equation $C: rx^2 + sy^2 + txy + ux + vy + w = 0$, where the six coefficients $\langle r, s, t, u, v, w \rangle$ completely characterize the curve. The sign of the expression $\Delta_C = 4rs - t^2$ determines the type of curve:

- If $\Delta_C > 0$ the curve is an ellipse. A circle is a special case of an ellipse, where $r = s$ and $t = 0$.
- If $\Delta_C = 0$ the curve is a parabola — an unbounded conic curve with a single connected branch. When $r = s = t = 0$ we have a line, which can be considered as a degenerate parabola.
- If $\Delta_C < 0$ the curve is a hyperbola. That is, it is comprised of two disconnected unbounded branches.

As the arrangement package is suitable for bounded curves, we consider bounded segments of conic curves, referred to as *conic arcs*. A conic arc a may be either (i) a full ellipse, or (ii) defined by the tuple $\langle C, p_s, p_t, o \rangle$, where C is a conic curve and p_s and p_t are two points on C (namely $C(p_s) = C(p_t) = 0$) that define the *source* and *target* of the arc, respectively. The arc is formed by traversing C from the source to the target going in the orientation specified by o , which is typically clockwise or counterclockwise orientation (but may also be collinear in case of degenerate conic curves).

We always assume that the conic coefficients $\langle r, s, t, u, v, w \rangle$ are rational. When dealing with linear curves (line segments and polylines), similar assumptions guarantee that all intersection points also have rational coordinates, such that the arrangement of such curves can be constructed and maintained using only rational arithmetic. Unfortunately, this does not hold for conic curves, as the coordinates of intersection points of two conic curves with rational coefficients are in general algebraic numbers of degree 4.¹² In addition, conic arcs may not necessarily be x -monotone, and must be split at points where the tangent to the arc is vertical. In the general case, such points typically have coordinates that are algebraic numbers of degree 2. It is therefore clear that we have to use different number types to represent the conic coefficients and the point coordinates. Note that as arrangement vertices induced by intersection points and points with vertical tangents are likely to have algebraic coordinates, we also allow the original endpoints of the input arcs p_s and p_t to have algebraic coordinates.

The `Arr_conic_traits_2<RatKernel, AlgKernel, NtTraits>` class template is designed for efficient handling of arrangements of bounded conic arcs. The template has three parameters, defined as follows:

- The `RatKernel` class is a geometric kernel, whose field type is an exact rational type. It is used to define basic geometric entities (e.g., a line segment or a circle) with rational coefficients. Typically we use one of the standard CGAL kernels, instantiated with the number type `NtTraits::Rational` (see below).
- The `AlgKernel` class is a geometric kernel whose field type is an exact algebraic type. It is used to define points with algebraic coordinates. Typically we use one of the standard CGAL kernels, instantiated with the number type `NtTraits::Algebraic` (see below).

¹²Namely, they are roots of polynomials with integer coefficients of degree 4. However, in some special cases, for example when handling only circles and circular arcs, the coordinates of the intersection points are only of degree 2, namely they are solutions of quadratic equations.

Figure 17.13: An arrangement of mixed conic arcs, as constructed in *ex_conics.C*.

- The *NtTraits* class (the number-type traits class) encapsulates all the numeric operations needed for performing the geometric computation carried out by the geometric traits class. It defines the *Integer*, *Rational* and *Algebraic* number-types, and supports several operations on these types, such as conversion between number types, solving quadratic equations and extracting the real roots of a polynomial with integer coefficients. It is highly recommended to use the *CORE_algebraic_number_traits* class, which is included in the arrangement package. It relies on the exact number types implemented in the *CORE* library and performs exact computations on the number types it defines.

The *Arr_conic_traits_2* models the *ArrangementTraits_2* and the *ArrangementLandmarkTraits_2* concepts. (It supports the landmark point-location strategy). Its *Point_2* type is derived from *AlgKernel::Point_2*, while the *Curve_2* type represents a bounded, not necessarily *x*-monotone, conic arc. The *X_monotone_curve_2* type is derived from *Curve_2*, but its constructors are to be used only by the traits class. Users should therefore construct only *Curve_2* objects and insert them into the arrangement using the *insert_curve()* or *insert_curves()* functions.

Conic arcs can be constructed from full ellipses or by specifying a supporting curve, two endpoints and an orientation. However, several constructors of *Curve_2* are available to allow for some special cases, such as circular arcs or line segments. The *Curve_2* (and the derived *X_monotone_curve_2*) classes also support basic access functions such as *source()*, *target()* and *orientation()*.

Examples for Arrangements of Conics

The following example demonstrates the usage of the various constructors for conic arcs. The resulting arrangement is depicted in Figure 17.13. Especially noteworthy are the constructor of a circular arc that accepts three points and the constructor that allows specifying approximate endpoints, where the exact endpoints are given explicitly as intersections of the supporting conic with two other conic curves. Also note that as the preconditions required by some of these constructors are rather complicated (see the Reference Manual for the details), a precondition violation does not cause the program to terminate — instead, an *invalid* arc is created. We can verify the validity of an arc by using the *is_valid()* method. Needless to say, inserting invalid arcs into an arrangement is not allowed.

```

/// \file examples/Arrangement_2/ex_conics.C
// Constructing an arrangement of various conic arcs.
#include <CGAL/basic.h>
```

```

    << ",    F = " << arr.number_of_faces() << std::endl;

return (0);
}

```

```
#endif
```

The last example in this section demonstrates how the conic-traits class can handle intersection points with multiplicity. The supporting curves of the two arcs, a circle centered at $(0, \frac{1}{2})$ with radius $\frac{1}{2}$, and the hyperbola $y = \frac{x^2}{1-x}$,¹³ intersect at the origin such that the intersection point has multiplicity 3 (note that they both have the same horizontal tangent at $(0,0)$ and the same curvature 1). In addition, they have another intersection point at $(\frac{1}{2}, \frac{1}{2})$ of multiplicity 1:

```
#!/ \file examples/Arrangement_2/ex_conic_multiplicities.C
// Handling intersection points with multiplicity between conic arcs.
#include <CGAL/basic.h>

#ifdef CGAL_USE_CORE
#include <iostream>

#endif

```

17.5.5 A Traits Class for Arcs of Rational Functions

A *rational function* is given by the equation $y = \frac{P(x)}{Q(x)}$, where P and Q are polynomials of arbitrary degrees. In particular, if $Q(x) = 1$, then the function is a simple polynomial function. A bounded *rational arc* is defined by the graph of a rational function over some interval $[x_{\min}, x_{\max}]$, where Q does not have any real roots in this interval (Thus, the arc does not contain any poles). Rational functions, and polynomial functions in particular, are not only interesting in their own right, they are also very useful for approximating or interpolating more complicated curves; see, e.g., [PTVF02, Chapter 3].

The computations with rational arcs are guaranteed to be robust and exact, assuming that the coefficient of the polynomials P and Q are rational numbers. The x -values that determine the interval over which the arc is defined can however be arbitrary algebraic numbers.

Using the `Arr_rational_traits_2<AlgKernel, NtTraits>` class template it is possible to construct and maintain arrangement of rational arcs. The template parameters are very similar to the ones used by the `Arr_conic_traits_2` class template; see the previous section. However, no rational kernel is needed. Also in this case it is recommended to use the `CORE_algebraic_number_traits` class, with a kernel instantiated with the *Algebraic* type defined by this class.

The `Arr_rational_traits_2` is a model of the `ArrangementTraits_2` concept (but not of the `ArrangementLandmarkTraits_2` concept, so it is not possible to use the landmark point-location strategy for arrangements of rational arcs). Its `Point_2` type is derived from `AlgKernel::Point_2`, while the `Curve_2` and `X_monotone_curve_2` types refer to the same class (note that a rational arc is always x -monotone). The traits class also defines the `Rat_vector` type, representing a vector of rational coefficients, (whose type is `NtTraits::Rational`). A rational arc can be constructed from a single vector of coefficients, specifying the polynomial P alone (and $Q(x) = 1$), or from two vectors of coefficients, specifying both P and Q .

Figure 17.14: An arrangement of four arcs of rational functions, as constructed in *ex_rational_functions.C*.

The following example demonstrates the construction of an arrangement of rational arcs depicted in Figure 17.14. Note the usage of the two constructors, for polynomial arcs and for rational arcs:

```

//! \file examples/Arrangement_2/ex_rational_functions.C
// Constructing an arrangement of arcs of rational functions.
#include <CGAL/basic.h>

#ifdef CGAL_USE_CORE
#include <iostream>
int main ()
{
    std::cout << "Sorry, this example needs CORE ..." << std::endl;
    return (0);
}
#else

#include <CGAL/Cartesian.h>
#include <CGAL/CORE_algebraic_number_traits.h>
#include <CGAL/Arr_rational_arc_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::CORE_algebraic_number_traits Nt_traits;
typedef Nt_traits::Rational Rational;
typedef Nt_traits::Algebraic Algebraic;
typedef CGAL::Cartesian<Algebraic> Alg_kernel;
typedef CGAL::Arr_rational_arc_traits_2<Alg_kernel,

              << "    V = " << arr.number_of_vertices()
              << ",    E = " << arr.number_of_edges()
              << ",    F = " << arr.number_of_faces() << std::endl;

    return 0;
}

#endif

```

17.5.6 Traits-Class Decorators

Geometric traits-class decorators allow users to attach auxiliary data to curves and to points. The data is automatically manipulated by the decorators and distributed to the constructed geometric entities. Note that additional information can alternatively be maintained by extending the vertex, halfedge, or face types provided by the DCEL class used by the arrangement; see the details in Section 17.7.

The arrangement package includes a generic traits-class decorator template named *Arr_curve_data_traits_2*<*BaseTraits*, *XMonotoneCurveData*, *Merge*, *CurveData*, *Convert*>. This decorator is used to attach a data field to curves and to *x*-monotone curves. It is parameterized by a base-traits class, which is one of the geometric traits classes described in the previous subsections, or a user-defined traits class. The curve-data decorator derives itself from the base-traits class, and in particular inherits its *Point_2* type. In addition:

- *Curve_2* is derived from the basic *BaseTraits::Curve_2* class, extending it by an extra field of type *CurveData*.
- *X_monotone_curve_2* is derived from the basic *BaseTraits::X_monotone_curve_2* class, extending it by an extra field of type *XMonotoneCurveData*.

Note that the *Curve_2* and *X_monotone_curve_2* are not the same, even if the *BaseTraits::Curve_2* and *BaseTraits::X_monotone_curve_2* are (as in the case of the segment-traits class for example). The extended curve types support the additional methods *data()* and *set_data()* for accessing and modifying the data field.

Users can create an extended curve (or an extended *x*-monotone curve) from a basic curve and a curve-data object. When curves are inserted into an arrangement, they may be split, and the decorator handles their data fields automatically:

- When a curve is subdivided into *x*-monotone subcurves, its data field of type *CurveData* is converted to an *XMonotoneCurveData* object *d* using the *Convert* functor. The object *d* is automatically associated with each of the resulting *x*-monotone subcurves.

Note that by default, the *CurveData* type is identical to the *XMonotoneCurveData* type (and the conversion functor *Convert* is trivially defined). Thus, the data field associated with the original curve is just duplicated and stored with the *x*-monotone subcurves.

- When an *x*-monotone curve is split into two, the decorator class automatically copies its data field to both resulting subcurves.
- When intersecting two *x*-monotone curves *c*₁ and *c*₂, the result may include overlapping sections, represented as *x*-monotone curves. In this case the data fields of *c*₁ and *c*₂ are merged into a single *XMonotoneCurveData* object, using the *Merge* functor, which is supplied as a parameter to the traits class-template. The resulting object is assigned to the data field of the overlapping subcurves.
- Merging two *x*-monotone curves is allowed only when (i) the two curves are geometrically mergeable — that is, the base-traits class allows to merge them — and (ii) the two curves store the same data field.

The *Arr_consolidated_curve_data_traits_2*<*BaseTraits*, *Data*> decorator specializes the generic curve-data decorator. It extends the basic *BaseTraits::Curve_2* by a single *Data* field, and the basic *BaseTraits::X_monotone_curve_2* with a *set* of (distinct) data objects. The *Data* type is required to support the equality operator, used to ensure that each set contains only distinct data objects with no duplicates. When a curve with a data field *d* is subdivided into *x*-monotone subcurves, each subcurve is associated with a set $S = \{d\}$. In case of an overlap between two *x*-monotone curves *c*₁ and *c*₂ with associated data sets *S*₁ and *S*₂, respectively, the overlapping subcurve is associated with the consolidated set $S_1 \cup S_2$.

Figure 17.15: An arrangement of six red and blue segments, as constructed in *ex_consolidated_curve_data.C*. Disks correspond to red–blue intersection points, while circles mark the endpoints of red–blue overlaps.

Examples

In the following example, we use *Arr_segment_traits_2* as our base-traits class, attaching an additional *color* field to the segments using the consolidated curve-data traits class. A color may be either *blue* or *red*. Having constructed the arrangement of colored segments, as depicted in Figure 17.15, we detect the vertices that have incident edges mapped to both blue and red segments. Thus, they correspond to red–blue intersection points. We also locate the edge that corresponds to overlaps between red and blue line segments:

```

//! \file examples/Arrangement_2/ex_consolidated_curve_data.C
// Associating a color attribute with segments using the consolidated
// curve-data traits.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>

}

```

In the following example, we use *Arr_polyline_traits_2* as our base-traits class, attaching an additional *name* field to each polyline using the generic curve-data traits class. In case of overlaps, we simply concatenate the names of the overlapping polylines. Also notice how we replace the curve associated with the edges that correspond to overlapping polylines with geometrically equivalent curves, but with a different data fields:

```

///! \file examples/Arrangement_2/ex_generic_curve_data.C
// Associating a name attribute with segments using the generic curve-data
// traits.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>

```

Figure 17.16: An arrangement of four polylines, named A–D, as constructed in *ex_generic_curve_data.C*.

```

17.6 The Notification Mechanism

For some applications it is essential to know exactly what happens inside a specific arrangement-instance. For example, when a new curve is inserted into an arrangement, it might be desired to keep track of the faces that are split due to this insertion operation. Other important examples are the point-location strategies that require auxiliary data-structures (see Section 17.3.1), which must be notified on various local changes in the arrangement, in order to keep their data structures up-to-date. The arrangement package offers a mechanism that uses *observers* (see [GHJV95]) that can be attached to an arrangement instance and receive notifications about the changes this arrangement goes through.

The `Arr_observer<Arrangement>` class-template is parameterized with an arrangement class. It stores a pointer to an arrangement object, and is capable of receiving notifications *just before* a structural change occurs in the arrangement and *immediately after* such a change takes place. `Arr_observer` serves as a base class for other observer classes and defines a set of virtual notification functions, with default empty implementations.

The set of functions can be divided into three categories, as follows:

1. Notifiers of changes that affect the entire topological structure of the arrangement. This category consists of two pairs that notify the observer of the following changes:

- The arrangement is cleared.
 - The arrangement is assigned with the contents of another arrangement.
2. Pairs of notifiers of a local change that occurs in the topological structure. Most notifier functions belong to this category. The relevant local changes include:
- A new vertex is constructed and associated with a point.
 - An edge¹⁴ is constructed and associated with an x -monotone curve.
 - An edge is split into two edges.
 - An existing face is split into two faces, as a consequence of the insertion of a new edge.
 - A hole is created in the interior of a face.
 - Two holes are merged to form a single hole, as a consequence of the insertion of a new edge.
 - A hole is moved from one face to another, as a consequence of a face split.
 - Two edges are merged into one edge.
 - Two faces are merged into one face, as a consequence of the removal of an edge that used to separate them.
 - One hole is split into two, as a consequence of the deletion of an edge that used to connect the two components.
 - A vertex is removed.
 - An edge is removed.
 - A hole is deleted from the interior of a face.
3. Notifiers about a change applied by a free (global) function. This category consists of a single pair of notifiers, namely *before_global_change()* and *after_global_change()*. Neither of these functions is invoked by methods of the *Arrangement_2* class. Instead, they are called by the free functions themselves. It is implied that no point-location queries (or any other queries for that matter) are issued between the calls to the notification functions above.

See the Reference Manual for a detailed specification of the *Arr_observer* class along with the exact prototypes of all notification functions.

Each arrangement object stores a (possibly empty) list of pointers to *Arr_observer* objects, and whenever one of the structural changes listed in the first two categories above is about to take place, the arrangement object performs a *forward* traversal on this list and invokes the appropriate function of each observer. After the change takes place the observer list is traversed in a *backward* manner (from tail to head), and the appropriate notification function is invoked for each observer. This allows the nesting of observer objects.

Concrete arrangement-observer classes should inherit from *Arr_observer*. When an observer is constructed, it is attached to a valid arrangement supplied to the observed constructor, or alternatively the observer can be attached to the arrangement at a later time. When this happens, the observer instance inserts itself into the observer list of the associated arrangement and starts receiving notifications whenever this arrangement changes thereafter. Naturally, the observer object unregisters itself by removing itself from this list just before it is destroyed.

The trapezoidal RIC and the landmark point-location strategies both use observers to keep their auxiliary data structures up-to-date. Besides them, users can define their own observer classes, by inheriting from the base observer class and overriding the relevant notification functions, as required by their applications.

The following example shows how to define and use an observer class. The observer in the example keeps track of the arrangement faces, and prints a message whenever a face is split into two due to the insertion of an edge, and whenever two faces merge into one due to the removal of an edge. The layout of the arrangement is depicted in Figure 17.17:

¹⁴The term “edge” refers here to a pair of twin half-edges.

Figure 17.17: An arrangement of five line segments, as constructed in *ex_observer.C*. The halfedge e_v (dashed) is eventually removed, so that the final arrangement consists of four faces (one unbounded and three bounded ones).

```

                << ",   F = " << arr.number_of_faces() << std::endl;

    return (0);
}

```

Observers are especially useful when the DCEL records are extended and store additional data, as they help updating this data on-line. See Section [17.7](#) for more details and examples.

17.7 Extending the DCEL

For many applications of the arrangement package it is necessary to store additional information (perhaps of non-geometric nature) with the arrangement cells. As vertices are associated with *Point_2* objects and edges (halfedge pairs) are associated with *X_monotone_curve_2* objects, both defined by the traits class, it is possible to extend the traits-class type by using a traits-class decorator, as explained in Section 17.5.6, which may be a sufficient solution for some applications. However, the DCEL faces are not associated with any geometric object, so it is impossible to extend them using a traits-class decorator. Extending the DCEL face records comes handy in such cases. As a matter of fact, it is possible to conveniently extend all DCEL records (namely vertices, halfedges and faces), which can also be advantageous for some applications.

All examples presented so far use the default *Arr_default_dcel<Traits>*. This is done implicitly, as this class serves as a default parameter for the *Arrangement_2* template. The default DCEL class just associates points with vertices and *x*-monotone curves with halfedge, but nothing more. In this section we show how to use alternative DCEL types to extend the desired DCEL records.

17.7.1 Extending the DCEL Faces

The *Arr_face_extended_dcel<Traits, FaceData>* class-template is used to associate auxiliary data field of type *FaceData* to each face record in the DCEL.

When an *Arrangement_2* object is parameterized by this DCEL class, its nested *Face* type is extended with the access function *data()* and with the modifier *set_data()*. Using these extra functions it is straightforward to access and maintain the auxiliary face-data field.

Note that the extra data fields must be maintained by the application programmers. They may choose to construct their arrangement, and only then go over the faces and attach the appropriate data fields to the arrangement faces. However, in some cases the face data can only be computed when the face is created (split from another face, or merged with another face). In such cases one can use an arrangement observer tailored for this task, which receives updates whenever a face is modified and sets its data field accordingly.

The next example constructs an arrangement that contains seven bounded faces induced by six line segments (see Figure 17.18). An observer gets notified each time a new face *f* is created and it associates *f* with a running index, (where the index of the unbounded face is 0). As a result, the faces are numbered according to their creation order, as one can easily verify by examining the insertion order of the segments:¹⁵

```
#!/ \file examples/Arrangement_2/ex_face_extension.C
// Extending the arrangement-face records.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_observer.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
```

¹⁵For simplicity, the particular observer used must be attached to an empty arrangement. It is not difficult however to modify the program to handle the general case of attaching a similar observer to a non-empty arrangement.

Figure 17.18: An arrangement of six line segments, as constructed in *ex_face_extension.C* and *ex_dcel_extension.C* (in *ex_dcel_extension.C* we treat the segments as directed, so they are drawn as arrows directed from the source to the target). The indices associated with the halfedges in *ex_face_extension.C* are shown in brackets.

```
typedef Traits_2::X_monotone_curve_2      Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, int> Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel> Arrangement_2;

// An arrangement observer, used to receive notifications of face splits and
// to update the indices of the newly created faces.
class Face_index_observer : public CGAL::Arr_observer<Arrangement_2>
{

            {
                std::cout << " --> " << curr->target()->point();
                ++curr;
            } while (curr != fit->outer_ccb());
            std::cout << std::endl;
        }
    }

    return (0);
}

```

17.7.2 Extending All DCEL Records

The `Arr_extended_dcel<Traits, VertexData, HalfedgeData, FaceData>` class-template is used to associate auxiliary data fields of types `VertexData`, `HalfedgeData`, and `FaceData` to each DCEL vertex, halfedge, and face record types, respectively.

When an `Arrangement_2` object is injected with this DCEL class, each one of its nested `Vertex`, `Halfedge` and `Face` classes is extended by the access function `data()` and by the modifier `set_data()`.

The next example shows how to use a DCEL with extended vertex, halfedge, and face records. In this example each vertex is associated with a color, which may be blue, red, or white, depending on whether the vertex is isolated, represents a segment endpoint, or whether it represents an intersection point. Each halfedge is associated with Boolean flag indicating whether its direction is the same as the direction of its associated segment (in this example segments are treated as directed objects). Each face is also extended to store the size of its outer boundary.

The constructed arrangement, depicted in Figure 17.18, is similar to the arrangement constructed in the previous example. Note that all auxiliary data fields are set during the construction phase. Also note that the data fields are properly maintained when the arrangement is copied to another arrangement instance:

```
//! \file examples/Arrangement_2/ex_dcel_extension.C
// Extending all DCEL records (vertices, edges and faces).

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>

enum Color {BLUE, RED, WHITE};

```

— advanced —

The various DCEL classes presented in this section are perfectly sufficient for most applications based on the arrangement package. However, users may also use their own implementation of a DCEL class to instantiate the *Arrangement_2* class-template, in case they need special functionality from their DCEL. Such a class must be a model of the concept *ArrangementDcel*, whose exact specification is listed in the Reference Manual.

17.8 Overlaying Arrangements

Assume that we are given two geographic maps represented as arrangements with some data objects attached to their faces, representing some geographic information — for example, a map of the annual precipitation in some country and a map of the vegetation in the same country. It is interesting to overlay the two maps to locate, for example, the regions where there is a pine forest and the annual precipitation is between 1000 mm and 1500 mm.

Computing the overlay of two planar arrangement is also useful for supporting Boolean set operations on polygons (or generalized polygons, see, e.g., [BEH⁺02]).

The function *overlay* (*arr_a*, *arr_b*, *ovl_arr*, *ovl_traits*) accepts two input arrangement instances *arr_a* and *arr_b*, and constructs their overlay instance *ovl_arr*. All three arrangements must use the same geometric primitives. In other words, their types must be defined using the same geometric traits-class. Let us assume that *arr_a* is of type *Arrangement_2*<*Traits*,*Dcel_A*>, *arr_b* is of type *Arrangement_2*<*Traits*,*Dcel_B*> and the resulting *ovl_arr* is of type *Arrangement_2*<*Traits*,*Dcel_R*>. The *ovl_traits* parameter is an instance of an *overlay traits-class*, which enables the creation of *Dcel_R* records in the overlaid arrangement from the DCEL features of *arr_a* and *arr_b* that they correspond to.

In principle, we distinguish between three levels of overlay:

Simple overlay: An overlay of two arrangements that store no additional data with their DCEL records. That is, they are defined using the default DCEL class *Arr_default_dcel*. Typically, the overlaid arrangement in this case stores no extra data with its DCEL records as well (or if it does, the additional data fields cannot be computed by the overlay operation), so by overlaying the two arrangement we just compute the arrangement of all curves that induce *arr_a* and *arr_b*. Note that the same result can be obtained using the

Figure 17.19: Overlaying two simple arrangements of line segments, as done in *ex_overlay.C* and *ex_face_extension_overlay.C*. In *ex_face_extension_overlay.C* the two bounded faces are considered as *marked*, and the octagonal face which is the intersection of the two marked faces is denoted by f_0 .

standard insertion operations, but users may choose to use overlay computation in order to achieve better running times.

The *Arr_default_overlay_traits* class should be used as an overlay traits-class for such simple overlay operations.

Face overlay: An overlay of two arrangements that store additional data fields with their faces (e.g., the geographic-map example given in the beginning of this section). The resulting overlaid arrangement typically also stores extraneous data fields with its faces, where the data field that is attached to an overlaid face can be computed from the data fields of the two faces (in *arr_a* and *arr_b*) that induce the overlaid face.

The *Arr_face_overlay_traits* class should be used as an overlay traits-class for face-overlay operations. It operates on arrangement, whose DCEL representation is based on the *Arr_face_extended_dcel* class-template (see Section 17.7.1). The face-overlay traits-class is parameterized by a functor that is capable of combining two face-data fields of types *Dcel_A::Face_data* and *Dcel_B::Face_data*, and computing the output *Dcel_R::Face_data* object. The overlay traits-class uses this functor to properly construct the overlaid faces.

Full overlay: An overlay of two arrangements that store additional data fields with all their DCEL records. That is, their DCEL classes are instantiations of the *Arr_extended_dcel* class-template (see Section 17.7.2), where the resulting arrangement also extends it DCEL records with data fields computed on the basis of the overlapping DCEL features of the two input arrangements.

In the following subsections we give some examples for the simple and the face-overlay operations and demonstrate how to use the auxiliary overlay traits-classes. For the full overlay operations users need to implement their specialized overlay traits-class, which models the *OverlayTraits* concept. The details of this concept are given in the Reference Manual.

17.8.1 Example for a Simple Overlay

The next program constructs two simple arrangements, as depicted in Figure 17.19 and computes their overlay:

```
///! \file examples/Arrangement_2/ex_overlay.C
```

```

// A simple overlay of two arrangements.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_overlay.h>
#include <CGAL/Arr_default_overlay_traits.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef CGAL::Arr_default_overlay_traits<Arrangement_2> Overlay_traits;

int main ()
{
    // Construct the first arrangement, containing a square-shaped face.
    Arrangement_2      arr1;

    Segment_2          s1 (Point_2(2, 2), Point_2(6, 2));
    Segment_2          s2 (Point_2(6, 2), Point_2(6, 6));
    Segment_2          s3 (Point_2(6, 6), Point_2(2, 6));
    Segment_2          s4 (Point_2(2, 6), Point_2(2, 2));

    insert_non_intersecting_curve (arr1, s1);
    insert_non_intersecting_curve (arr1, s2);
    insert_non_intersecting_curve (arr1, s3);
    insert_non_intersecting_curve (arr1, s4);

    // Construct the second arrangement, containing a rhombus-shaped face.
    Arrangement_2      arr2;

    Segment_2          t1 (Point_2(4, 1), Point_2(7, 4));
    Segment_2          t2 (Point_2(7, 4), Point_2(4, 7));
    Segment_2          t3 (Point_2(4, 7), Point_2(1, 4));
    Segment_2          t4 (Point_2(1, 4), Point_2(4, 1));

    insert_non_intersecting_curve (arr2, t1);
    insert_non_intersecting_curve (arr2, t2);
    insert_non_intersecting_curve (arr2, t3);
    insert_non_intersecting_curve (arr2, t4);

    // Compute the overlay of the two arrangements.
    Arrangement_2      overlay_arr;
    Overlay_traits      overlay_traits;

    overlay (arr1, arr2, overlay_arr, overlay_traits);

    // Print the size of the overlaid arrangement.
    std::cout << "The overlaid arrangement size:" << std::endl
                << "    V = " << overlay_arr.number_of_vertices()
                << ",    E = " << overlay_arr.number_of_edges()

```

```

        << ", F = " << overlay_arr.number_of_faces() << std::endl;

    return (0);
}

```

17.8.2 Example for a Face Overlay

The following example shows how to compute the intersection of two polygons using the *overlay()* function. It uses a face-extended DCEL class to define our arrangement class. The DCEL extends each face with a Boolean flag. A polygon is represented as a *marked* arrangement face, (whose flag is set). The example uses a face-overlay traits class, instantiated with a functor that simply performs a logical *and* operations on Boolean flags. As a result, a face in the overlaid arrangement is marked only when it corresponds to an overlapping region of two marked cells in the input arrangements. Namely, it is part of the intersection of the two polygons.

The example computes the intersection between a square and a rhombus, (which is actually also a square). The resulting polygon is an octagon, denoted by f_0 in Figure 17.19:

```

//! \file examples/Arrangement_2/ex_face_extension_overlay.C
// A face overlay of two arrangement with extended face records.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_overlay.h>
#include <CGAL/Arr_default_overlay_traits.h>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, bool> Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>      Arrangement_2;
typedef CGAL::Arr_face_overlay_traits<Arrangement_2,
                                     Arrangement_2,
                                     Arrangement_2,
                                     std::logical_and<bool> > Overlay_traits;

int main ()
{
    // Construct the first arrangement, containing a square-shaped face.
    Arrangement_2 arr1;

    Segment_2 s1 (Point_2(2, 2), Point_2(6, 2));
    Segment_2 s2 (Point_2(6, 2), Point_2(6, 6));
    Segment_2 s3 (Point_2(6, 6), Point_2(2, 6));
    Segment_2 s4 (Point_2(2, 6), Point_2(2, 2));

    insert_non_intersecting_curve (arr1, s1);
    insert_non_intersecting_curve (arr1, s2);
    insert_non_intersecting_curve (arr1, s3);

```

```

insert_non_intersecting_curve (arr1, s4);

// Mark just the bounded face.
Arrangement_2::Face_iterator fit;

CGAL_assertion (arr1.number_of_faces() == 2);
for (fit = arr1.faces_begin(); fit != arr1.faces_end(); ++fit)
    fit->set_data (fit != arr1.unbounded_face());

// Construct the second arrangement, containing a rhombus-shaped face.

insert_non_intersecting_curve (arr2, t2);
insert_non_intersecting_curve (arr2, t3);
insert_non_intersecting_curve (arr2, t4);

// Mark just the bounded face.
CGAL_assertion (arr2.number_of_faces() == 2);
for (fit = arr2.faces_begin(); fit != arr2.faces_end(); ++fit)
    fit->set_data (fit != arr2.unbounded_face());

// Compute the overlay of the two arrangements, marking only the faces that
// are intersections of two marked faces in arr1 and arr2, respectively.
Arrangement_2 overlay_arr;
Overlay_traits overlay_traits;

overlay (arr1, arr2, overlay_arr, overlay_traits);

// Go over the faces of the overlaid arrangement and print just the marked
// ones.
Arrangement_2::Ccb_halfedge_circulator curr;

std::cout << "The union is: ";
for (fit = overlay_arr.faces_begin(); fit != overlay_arr.faces_end(); ++fit)
{
    if (! fit->data())
        continue;

    curr = fit->outer_ccb();
    std::cout << curr->source()->point();
    do
    {
        std::cout << " --> " << curr->target()->point();
        ++curr;
    } while (curr != fit->outer_ccb());
    std::cout << std::endl;
}

```

```

    return (0);
}

```

17.9 Storing the Curve History

As stated at the beginning of this chapter (Section 17.1), when one constructs an arrangement induced by a set C of arbitrary planar curves, she or he constructs a collection C'' of x -monotone subcurves of C that are pairwise disjoint in their interior, and these subcurves are associated with the arrangement edges (more precisely, with the DCEL halfedges). Doing so, the connection between the originating input curves and the arrangement edges is lost. This loss might be acceptable for some applications. However, in many practical cases it is important to determine the input curves that give rise to the final subcurves.

The *Arrangement_with_history_2*<*Traits*,*Dcel*> class-template extends the *Arrangement_2* class by keeping an additional container of input curves representing C , and by maintaining a cross-mapping between these curves and the arrangement edges they induce. The traits class that is used for instantiating the template should be a model of the *ArrangementTraits_2* concept (see Section 17.4.1). That is, it should define the *Curve_2* type (and not just the *X_monotone_curve_2* type). The *Dcel* parameter should model the *ArrangementDcel* concept. Users can use the default DCEL class or an extended DCEL class according to their needs.

17.9.1 Traversing an Arrangement with History

The *Arrangement_with_history_2* class extends the *Arrangement_2* class, thus all the iterator and circulator types that are defined by the arrangement class are also available in *Arrangement_with_history_2*. The reader is referred to Section 17.2.2 for a comprehensive review of these functions.

As mentioned above, the *Arrangement_with_history_2* class maintains a container of input curves, which can be accessed using curve handles. The member function *number_of_curves()* returns the number of input curves stored in the container, while *curves_begin()* and *curves_end()* return *Arrangement_with_history_2::Curve_iterator* objects that define the valid range of curves that induce the arrangement. The value type of this iterator is *Curve_2*. Moreover, the curve-iterator type is equivalent to *Arrangement_with_history_2::Curve_handle*, which is used for accessing the stored curves. Conveniently, the corresponding constant-iterator and constant-handle types are also defined.

As mentioned in the previous paragraph, a *Curve_handle* object *ch* serves as a pointer to a curve stored in an arrangement-with-history instance *arr*. Using this handle, it is possible to obtain the number of arrangement edges this curve induces by calling *arr.number_of_induced_edges(ch)*. The functions *arr.induced_edges_begin(ch)* and *arr.induced_edges_end(ch)* return iterators of type *Arrangement_with_history_2::Induced_edges_iterator* that define the valid range of edges induced by *ch*. The value type of these iterators is *Halfedge_handle*. It is thus possible to traverse all arrangement edges induced by an input curve.

It is also important to be able to perform the inverse mapping. Given an arrangement edge, we would like to be able to determine which input curve induces it. In case the edge represents an overlap of several curves, we should be able to trace all input curves that overlap over this edge. The *Arrangement_with_history_2* class is extended by several member functions that enable such an inverse mapping. Given a halfedge handle *e* in an arrangement with history *arr*, then *arr.number_of_originating_curves(e)* returns the number of curves that induce the edge (which should be 1 in non-degenerate cases, and 2 or more in case of overlaps), while *arr.originating_curves_begin(e)* and *arr.originating_curves_end(e)* return *Arrangement_with_history_2::Originating_curve_iterator* objects that define the range of curves that induce *e*. The value type of these iterator is *Curve_2*.

It is possible to overlay two *Arrangement_with_history_2* instances instantiated by the same traits class. In this case, the resulting arrangement will store a consolidated container of input curves, and automatically preserve the cross-mapping between the arrangement edges and the consolidated curve set. Users can employ an overlay-traits class to maintain any type of auxiliary data stored with the DCEL features (see Section 17.8).

17.9.2 Modifying an Arrangement with History

As the *Arrangement_with_history_2* class extends the *Arrangement_2* class, it inherits the fundamental modification operations, such as *assign()* and *clear()*, from it. The vertex-manipulation functions are also inherited and supported (see Sections 17.2.3 and 17.4.1 for the details). However, there are some fundamental differences between the interfaces of the two classes, which we highlight in this subsection.

The most significant difference between the arrangement-with-history class and the basic arrangement class is the way they handle their input curves. *Arrangement_with_history_2* always stores the *Curve_2* objects that induce it, thus it is impossible to insert *x*-monotone curves into an arrangement with history. The free *insert_non_intersecting_curve()* and *insert_x_monotone_curve()* (as well as their aggregated versions) are therefore not available for arrangement-with-history instances and only the free *insert_curve()* and *insert_curves()* functions (the incremental insertion function and the aggregated insertion function) are supported — see also Section 17.4.1. Notice however that while the incremental insertion function *insert_curve(arr,c)* for an *Arrangement_2* object *arr* does not have a return value, the corresponding arrangement-with-history function returns a *Curve_handle* to the inserted curve.

As we are able to keep track of all edges induced by an input curve, we also provide a free function that removes a curve from an arrangement. By calling *remove(arr,ch)*, where *ch* is a valid curve handle, the given curve is deleted from the curve container, and all edges induced solely by this curve (i.e., excluding overlapping edges) are removed from the arrangement. The function returns the number of edges that have been removed.

In some cases, users may need to operate directly on the arrangement edges. We first mention that the specialized insertion functions (see Section 17.2.3) are not supported, as they accept *x*-monotone curves. Insertion can only be performed via the free insertion-functions. The other edge-manipulation functions (see Section 17.2.3) are however available, but have a different interface that does not use *x*-monotone curves:

- Invoking *split_edge(e,p)* splits the edge *e* at a given point *p* that lies in its interior.
- Invoking *merge_edge(e1,e2)* merges the two given edges. There is a precondition that *e1* and *e2* shared a common end-vertex of degree 2, and that the *x*-monotone subcurves associated with these edges are mergeable.
- It is possible to remove an edge by simply invoking *remove_edge(e)*.

In all cases, the maintenance of cross-pointers for the appropriate input curves will be done automatically.

It should be noted that it is possible to attach observers to an arrangement-with-history instance in order to get detailed notifications of the changes the arrangements undergoes (see Section 17.6 for the details).

17.9.3 Examples

In the following example we construct a simple arrangement of six line segments, as depicted in Figure 17.20, while maintaining the curve history. The example demonstrates the usage of the special traversal functions. It also shows how to issue point-location queries on the resulting arrangement, using the auxiliary function *point_location_query()* defined in the header file *point_location_utils.h* (see also Section 17.3.1).

Figure 17.20: An arrangement with history as constructed in *ex_curve_history.C*. Note that s_1 and s_3 overlap over two edges. The point-location query points are drawn as lightly shaded dots.

```
// file: examples/Arrangement_2/ex_curve_history.C
// Constructing an arrangement with curve history.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_with_history_2.h>
#include <CGAL/Arr_trapezoid_ric_point_location.h>

         ocit != arr.originating_curves_end (eit); ++ocit)
    {
        std::cout << " [" << *ocit << "]" << std::flush;
    }
    std::cout << std::endl;
}

// Perform some point-location queries:
Point_location  pl (arr);

Point_2        p1 (4, 6);
point_location_query (pl, p1);
Point_2        p2 (6, 2);
point_location_query (pl, p2);
Point_2        p3 (2, 4);
point_location_query (pl, p3);

return (0);
}

```

The following example demonstrates the usage of the free *remove()* function. We construct an arrangement of nine circles, while keeping a handle to each inserted circle. We then remove the large circle C_0 , which induces 18 edges, as depicted in Figure 17.21. The example also shows how to use the *split_edge()* and *merge_edge()* functions when operating on an arrangement-with-history instance:

```

///! \file examples/Arrangement_2/ex_edge_manipulation_curve_history.C
// Removing curves and manipulating edges in an arrangement with history.

```

Figure 17.21: An arrangement with history of nine circle as constructed in *ex_edge_manipulation_curve_history.C*. Note the vertical tangency points of C_0 , marked as dark dots, which subdivide this circle into an upper half and a lower half, each consists of 9 edges. The large circle C_0 is eventually removed from the arrangement, with all 18 edges it induces.

```

17.10 Input/Output Functions

In some cases, we would like to reuse an arrangement instance constructed by our application in the future — for example, our arrangement may represent a very complicated geographical map and we have various applications that need to answer point-location queries on this map. Naturally, we can store the set of curves that induces the arrangement, but this implies that we need to construct the arrangement from scratch each time we need to reuse it. A more efficient solution would be to save the arrangement to a file, so that other application can reread it from there.

We provide an *inserter* (the `<<` operator) and an *extractor* (the `>>` operator) for the `Arrangement_2<Traits,Dcel>` class, such that an arrangement instance can be inserted into an output stream or read from an input stream. The arrangement is written using a simple predefined textual format that encodes the arrangement topology, as well as all geometric entities associated with vertices and edges.

To use the input/output operators, we require that the `Point_2` type and the `X_monotone_curve_2` type defined by the traits class both support the `<<` and `>>` operators. The `Arr_conic_traits_2` class (see Section 17.5.4) and the `Arr_rational_arc_traits_2` class (see Section 17.5.5) currently do not provide these operator for the geometric types they define, so only arrangements of line segments or of polylines can be written or read.

The following example constructs the arrangement depicted in Figure 17.7 and writes it to an output file. It also demonstrates how to re-read the arrangement from a file:

```
#!/ \file examples/Arrangement_2/ex_io.C
// Using the arrangement I/O operators.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/IO/Arr_iostream.h>
#include <fstream>

#include "point_location_utils.h"

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;

int main ()
{
    // Construct the arrangement.
    Arrangement_2 arr;

    construct_segments_arr (arr);

    std::cout << "Writing an arrangement of size:" << std::endl
              << "   V = " << arr.number_of_vertices()
              << ",   E = " << arr.number_of_edges()
              << ",   F = " << arr.number_of_faces() << std::endl;

    // Write the arrangement to a file.
    std::ofstream out_file ("arr_ex_io.dat");
```

```

out_file << arr;
out_file.close();

// Read the arrangement from the file.
Arrangement_2 arr2;
std::ifstream in_file ("arr_ex_io.dat");

in_file >> arr2;
in_file.close();

std::cout << "Read an arrangement of size:" << std::endl
          << "   V = " << arr2.number_of_vertices()
          << ",   E = " << arr2.number_of_edges()
          << ",   F = " << arr2.number_of_faces() << std::endl;

return (0);
}

```

advanced

17.10.1 Arrangements with Auxiliary Data

The inserter and extractor both ignore any auxiliary data stored with the arrangement features, thus they are ideal for arrangements instantiated using the *Arr_default_dcel* class. However, as explained in Section 17.7, one can easily extend the arrangement faces by using the *Arr_face_extended_dcel* template, or extend all DCEL records by using the *Arr_extended_dcel* template. In such cases, it may be crucial that the auxiliary data fields are written to the file or read from there.

The arrangement package includes the free functions *write(arr, os, formatter)*, which writes the arrangement *arr* to an output stream *os*, and *read(arr, os, formatter)*, which reads the arrangement *arr* from an input stream *is*. Both operations are performed using a *formatter* object, which defines the I/O format. The package contains three formatter classes:

- *Arr_text_formatter<Arrangement>* defines a simple textual I/O format for the arrangement topology and geometry, disregarding any auxiliary data that may be associated with the arrangement features. This is the default formatter used by the arrangement inserter and the arrangement extractor, as defined above.
- *Arr_face_extended_text_formatter<Arrangement>* operates on arrangements whose DCEL representation is based on the *Arr_face_extended_dcel<Traits, FaceData>* class (see Section 17.7.1). It supports reading and writing the auxiliary data objects stored with the arrangement faces provided that the *FaceData* class supports an inserter and an extractor.
- *Arr_extended_dcel_text_formatter<Arrangement>* operates on arrangements whose DCEL representation is based on the *Arr_extended_dcel<Traits, VertexData, HalfedgeData, FaceData>* class (see Section 17.7.2). It supports reading and writing the auxiliary data objects stored with the arrangement vertices, edges and faces, provided that the *VertexData*, *HalfedgeData* and *FaceData* classed all have inserters and extractors.

The following example constructs the same arrangement as the example *ex_dcel_extension* does (see Section 17.7.2) which is depicted in Figure 17.18, and writes it to an output file. It also demonstrates how to re-read the arrangement from a file:

```

///! \file examples/Arrangement_2/ex_dcel_extension_io.C
// Using the I/O operators for arrangements with extended DCEL records.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/IO/Arr_text_formatter.h>
#include <CGAL/IO/Arr_iostream.h>

}

// Go over all arrangement edges and set their flags.
Arrangement_2::Edge_iterator      eit;
bool                              flag;

for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit)
{
    // Check if the halfedge has the same direction as its associated
    // segment. Note that its twin always has an opposite direction.
    flag = (eit->source()->point() == eit->curve().source());
    eit->set_data (flag);
    eit->twin()->set_data (!flag);
}

// Go over all arrangement faces and print their outer boundary and indices.
Arrangement_2::Face_iterator      fit;
Arrangement_2::Ccb_halfedge_circulator      curr;
int                              boundary_size;

for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit)
{
    boundary_size = 0;
    if (! fit->is_unbounded())
    {
        curr = fit->outer_ccb();
    }
}

```

```

    do
    {
        ++boundary_size;
        ++curr;
    } while (curr != fit->outer_ccb());
    }
    fit->set_data (boundary_size);
}

// Write the arrangement to a file.
std::ofstream    out_file ("arr_ex_dcel_io.dat");
Formatter        formatter;

write (arr, out_file, formatter);
out_file.close();

// Read the arrangement from the file.
Arrangement_2    arr2;
std::ifstream    in_file ("arr_ex_dcel_io.dat");

read (arr2, in_file, formatter);
in_file.close();

std::cout << "The arrangement vertices: " << std::endl;
for (vit = arr2.vertices_begin(); vit != arr2.vertices_end(); ++vit)
    std::cout << '(' << vit->point() << ") - " << vit->data() << std::endl;

return (0);
}

```

External users may write their own formatter classes by implementing models to the *ArrangementInputFormatter* and the *ArrangementOutputFormatter*, as defined in the Reference Manual. Doing so, they can define other I/O formats, such as an XML-based format or a binary format.

advanced

17.10.2 Arrangements with Curve History

In Section 17.9 we introduced the *Arrangement_with_history_2<Traits,Dcel>* class that stores the set of curves inducing the arrangement and maintains the relations between these curves and the edges they induce. Naturally, when reading or writing an arrangement-with-history instance we would like this information to be written to the output stream or retrieved from the input stream alongside with the basic arrangement structure.

The arrangement package supplies an inserter and an extractor for the *Arrangement_with_history_2<Traits,Dcel>* class. The arrangement is represented using a simple predefined textual format, where we require that the *Curve_2* type defined by the traits class — as well as the *Point_2* type and the *X_monotone_curve_2* types — support the << and >> operators.

The following example constructs the same arrangement as example *ex_curve_history* does (see Section 17.9.3) which is depicted in Figure 17.20, and writes it to an output file. It also demonstrates how to re-read the arrangement-with-history from a file:

```

/// \file examples/Arrangement_2/ex_io_curve_history.C
// Using the arrangement-with-history I/O operators.

#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_with_history_2.h>
#include <CGAL/IO/Arr_with_history_iostream.h>
#include <fstream>

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::Curve_2                     Segment_2;
typedef CGAL::Arrangement_with_history_2<Traits_2> Arr_with_hist_2;

int main ()
{
    Arr_with_hist_2  arr;

    // Insert six additional segments aggregately:
    Segment_2        segs[6];
    segs[0] = Segment_2 (Point_2 (2, 6), Point_2 (7, 1));
    segs[1] = Segment_2 (Point_2 (3, 2), Point_2 (3, 5));
    segs[2] = Segment_2 (Point_2 (2, 3), Point_2 (5, 3));
    segs[3] = Segment_2 (Point_2 (2, 6), Point_2 (7, 1));
    segs[4] = Segment_2 (Point_2 (0, 0), Point_2 (2, 6));
    segs[5] = Segment_2 (Point_2 (3, 4), Point_2 (6, 4));
    insert_curves (arr, segs, segs + 6);

    std::cout << "Writing an arrangement of "
                << arr.number_of_curves() << " input segments:" << std::endl
                << "    V = " << arr.number_of_vertices()
                << ",    E = " << arr.number_of_edges()
                << ",    F = " << arr.number_of_faces() << std::endl;

    // Write the arrangement to a file.
    std::ofstream      out_file ("arr_ex_io_hist.dat");

    out_file << arr;
    out_file.close();

    // Read the arrangement from the file.
    Arr_with_hist_2    arr2;
    std::ifstream      in_file ("arr_ex_io_hist.dat");

    in_file >> arr2;
    in_file.close();

    std::cout << "Read an arrangement of "
                << arr2.number_of_curves() << " input segments:" << std::endl

                << ",    E = " << arr2.number_of_edges()
                << ",    F = " << arr2.number_of_faces() << std::endl;

```

```

    return (0);
}

```

— *advanced* —

The arrangement package also includes the free functions *write(arr, os, formatter)* and *read(arr, os, formatter)* that operate on a given arrangement-with-history instance *arr*. Both functions are parameterized by a *formatter* object, which define the I/O format. The package contains a template called, *Arr_with_hist_text_formatter<ArrangementFormatter>*, which extends an arrangement formatter class (see Section 17.10.1) and defines a simple textual input/output format.

— *advanced* —

17.11 Adapting to BOOST Graphs

BOOST¹⁶ is a collection of portable C++ libraries that extend the Standard Template Library (STL). The BOOST Graph Library (BGL), which one of the libraries in the collection, offers an extensive set of generic graph algorithms parameterized through templates. As our arrangements are embedded as planar graphs, it is only natural to extend the underlying data structure with the interface that the BGL expects, and gain the ability to perform the operations that the BGL supports, such as shortest-path computation. This section describes how apply the graph algorithms implemented in the BGL to *Arrangement_2* instances.

An instance of *Arrangement_2* is adapted to a BOOST graph through the provision of a set of free functions that operate on the arrangement features and conform with the relevant BGL concepts. Besides the straightforward adaptation, which associates a vertex with each DCEL vertex and an edge with each DCEL halfedge, the package also offer a *dual* adaptor, which associates a graph vertex with each DCEL face, such that two vertices are connected, iff there is a DCEL halfedge that connects the two corresponding faces.

17.11.1 The Primal Arrangement Representation

Arrangement instances are adapted to BOOST graphs by specializing the *boost::graph_traits* template for *Arrangement_2* instances. The graph-traits states the graph concepts that the arrangement class models (see below) and defines the types required by these concepts.

In this specialization the *Arrangement_2* vertices correspond to the graph vertices, where two vertices are adjacent if there is at least one halfedge connecting them. More precisely, *Arrangement_2::Vertex_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. As halfedges are directed, we consider the graph to be directed as well. Moreover, as several interior-disjoint *x*-monotone curves (say circular arcs) may share two common endpoints, inducing an arrangement with two vertices that are connected with several edges, we allow parallel edges in our BOOST graph.

Given an *Arrangement_2* instance, we can efficiently traverse its vertices and halfedges. Thus, the arrangement graph is a model of the concepts *VertexListGraph* and *EdgeListGraph* introduced by the BGL. At the same time, we use an iterator adapter of the circulator over the halfedges incident to a vertex (*Halfedge_around_vertex_circulator* — see Section 17.2.2), so it is possible to go over the ingoing and outgoing edges of a vertex in linear time. Thus, our arrangement graph is a model of the concept *BidirectionalGraph* (this concept refines *IncidenceGraph*, which requires only the traversal of outgoing edges).

¹⁶See also BOOST's homepage at: www.boost.org.

Figure 17.22: An arrangement of 7 line segments, as constructed by *ex_bgl_primal_adapter.C* and *ex_bgl_dual_adapter.C*. The breadth-first visit times for the arrangement faces, starting from the unbounded face f_0 , are shown in brackets.

It is important to notice that the vertex descriptors we use are *Vertex_handle* objects and *not* vertex indices. However, in order to gain more efficiency in most BGL algorithm, it is better to have them indexed $0, 1, \dots, (n - 1)$, where n is the number of vertices. We therefore introduce the *Arr_vertex_index_map*<Arrangement> class-template, which maintains a mapping of vertex handles to indices, as required by the BGL. An instance of this class must be attached to a valid arrangement vertex when it is created. It uses the notification mechanism (see Section 17.6) to automatically maintain the mapping of vertices to indices, even when new vertices are inserted into the arrangement or existing vertices are removed.

In most algorithm provided by the BGL, the output is given by *property maps*, such that each map entry corresponds to a vertex. For example, when we compute the shortest paths from a given source vertex s to all other vertices we can obtain a map of distances and a map of predecessors — namely for each v vertex we have its distance from s and a descriptor of the vertex that precedes v in the shortest path from s . If the vertex descriptors are simply indices, one can use vectors to efficiently represent the property maps. As this is not the case with the arrangement graph, we offer the *Arr_vertex_property_map*<Arrangement,Type> template allows for an efficient mapping of *Vertex_handle* objects to properties of type *Type*. Note however that unlike the *Arr_vertex_index_map* class, the vertex property-map class is not kept synchronized with the number of vertices in the arrangement, so it should not be reused in calls to BGL functions in case the arrangement is modified in between these calls.

In the following example we construct an arrangement of 7 line segments, as shown in Figure 17.22, then use Dijkstra's shortest-paths algorithm from the BGL to compute the graph distance of all vertices from the leftmost vertex in the arrangement v_0 . Note the usage of the *Arr_vertex_index_map* and the *Arr_vertex_property_map* classes. The latter one, instantiated by the type *double* is used to map vertices to their distances from v_0 .

```

17.11.2 The Dual Arrangement Representation

It is possible to give a dual graph representation for an arrangement instance, such that each arrangement face corresponds to a graph vertex and two vertices are adjacent iff the corresponding faces share a common edge on their boundaries. This is done by specializing the *boost::graph_traits* template for *Dual<Arrangement_2>* instances, where *Dual<Arrangement_2>* is a template specialization that gives a dual interpretation to an arrangement instance.

In dual representation, *Arrangement_2::Face_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. We treat the graph edges as directed, such that a halfedge *e* is directed from *f*₁, which is its incident face, to *f*₂, which is the incident face of its twin halfedge. As two arrangement faces may share more than a single edge on their boundary, we allow parallel edges in our BOOST graph. As is the case in the primal graph, the dual arrangement graph is also a model of the concepts *VertexListGraph*, *EdgeListGraph* and *BidirectionalGraph* (thus also of *IncidenceGraph*).

Since we use *Face_handle* objects as the vertex descriptors, we define the *Arr_face_index_map<Arrangement>* class-template, which maintains an efficient mapping of face handles to indices. We also provide the template *Arr_face_property_map<Arrangement,Type>* for associating arbitrary data with the arrangement faces.

In the following example we construct the same arrangement as in example *ex_bgl_primal_adapter.C* (see Figure 17.22), and perform breadth-first search on the graph faces, starting from the unbounded face. We extend the DCEL faces with an unsigned integer, marking the discover time of the face and use a breadth-first-search visitor to obtain these times and update the faces accordingly:

```

///! \file examples/Arrangement_2/ex_bgl_dual_adapter.C

```

```

// Adapting the dual of an arrangement to a BGL graph.

}

return (0);
}

```

17.12 How To Speed Up Your Computation

Before the specific tips, we remind you that compiling programs with debug flags disabled and with optimization flags enabled significantly reduces the running time.

1. When the curves to be inserted into an arrangement are x -monotone and pairwise disjoint in their interior to start with, then it is more efficient (in running time) and less demanding (in traits-class functionality) to use the non-intersection insertion-functions instead of the general ones; e.g., *insert_x_monotone_curve()*.
2. When the curves to be inserted into an arrangement are segments that are pairwise disjoint in their interior, it is more efficient to use the traits class *Arr_non_caching_segment_traits_2* rather than the default one

(*Arr_segment_traits_2*).

If the segments may intersect each other, the default traits class *Arr_segment_traits_2* can be safely used with the somehow limited number type *Quotient<MP_float>*.

On rare occasions the traits class *Arr_non_caching_segment_traits_2* exhibits slightly better performance than the default one (*Arr_segment_traits_2* even when the segments intersect each other, due to the small overhead of the latter (optimized) traits class. (For example, when the the so called LEDA rational kernel is used).

3. Prior knowledge of the combinatorial structure of the arrangement can be used to accelerate operations that insert x -monotone curves, whose interior is disjoint from existing edges and vertices of the arrangement. The specialized insertion functions, i.e., *insert_in_face_interior()*, *insert_from_left_vertex()*, *insert_from_right_vertex()*, and *insert_at_vertices()* can be used according to the available information. These functions hardly involve any geometric operations, if at all. They accept topologically related parameters, and use them to operate directly on the DCEL records, thus saving algebraic operations, which are especially expensive when high-degree curves are involved.

A polygon, represented by a list of segments along its boundary, can be inserted into an empty arrangement as follows. First, one segment is inserted using *insert_in_face_interior()* into the unbounded face. Then, a segment with a common end point is inserted using either *insert_from_left_vertex()* or *insert_from_right_vertex()*, and so on with the rest of the segments except for the last, which is inserted using *insert_at_vertices()*, as both endpoints of which are the mapping of known vertices.

4. The main trade-off among point-location strategies, is between time and storage. Using the naive or walk strategies, for example, takes more query time but does not require preprocessing or maintenance of auxiliary structures and saves storage space.
5. If point-location queries are not performed frequently, but other modifying functions, such as removing, splitting, or merging edges are, then using a point-location strategy that does not require the maintenance of auxiliary structures, such as the the naive or walk strategies, is preferable.
6. There is a trade-off between two modes of the trapezoidal RIC strategy that enables the user to choose whether preprocessing should be performed or not. If preprocessing is not used, the creation of the structure is faster. However, for some input sequences the structure might be unbalanced and therefore queries and updates might take longer, especially, if many removal and split operations are performed.
7. When the curves to be inserted into an arrangement are available in advance (as opposed to supplied on-line), it is advised to use the more efficient aggregate (sweep-based) insertion over the incremental insertion; e.g., *insert_curves()*.
8. The various traits classes should be instantiated with an exact number type to ensure robustness, when the input of the operations to be carried out might be degenerate, although inexact number types could be used at the user's own risk.
9. Maintaining short bit-lengths of coordinate representations may drastically decrease the time consumption of arithmetic operations on the coordinates. This can be achieved by caching certain information or normalization (of rational numbers). However, both solutions should be used cautiously, as the former may lead to an undue space consumption, and indiscriminate normalization may considerably slow down the overall process.
10. Geometric functions (e.g., traits methods) dominate the time consumption of most operations. Thus, calls to such function should be avoided or at least their number should be decreased, perhaps at the expense of increased combinatorial-function calls or increased space consumption. For example, repetition of geometric-function calls could be avoided by storing the results obtained by the first call, and reusing them when needed.

Design and Implementation History

The code of this package is the result of a long development process. Initially (and until version 3.1), the code was spread among several packages, namely *Topological_map*, *Planar_map_2*, *Planar_map_with_intersections_2* and *Arrangement_2*, that were developed by :

Ester Ezra, Eyal Flato, Efi Fogel, Dan Halperin, Iddo Hanniel, Idit Haran, Shai Hirsch, Eugene Lipovetsky, Oren Nechushtan, Sigal Raab, Ron Wein, Baruch Zukerman and Tali Zvi.

In version 3.2, as part of the ACS project, the packages have gone through a major re-design, resulting in an improved *Arrangement_2* package. The code of the new package was restructured and developed by :
Efi Fogel, Idit Haran, Ron Wein and Baruch Zukerman.

2D Arrangements

Reference Manual

Ron Wein, Efi Fogel, Baruch Zukerman, and Dan Halperin

Given a set C of planar curves, the *arrangement* $\mathcal{A}(C)$ is the subdivision of the plane induced by the curves in C into maximally connected cells. The cells can be 0-dimensional (*vertices*), 1-dimensional (*edges*) or 2-dimensional (*faces*).

The class `Arrangement_2<Traits,Dcel>` encapsulates a data structure that maintains arrangements of arbitrary bounded planar curves. It comes with a variety of algorithms that operate on planar arrangement, such as point-location queries and overlay computations, which are implemented as peripheral classes or as free (global) functions.

CGAL::Arrangement_2<Traits,Dcel>

Definition

An object *arr* of the class *Arrangement_2<Traits,Dcel>* represents the planar subdivision induced by a set of *x*-monotone curves and isolated points into maximally connected cells. The arrangement is represented as a doubly-connected edge-list (DCEL) such that each DCEL vertex is associated with a point of the plane and each edge is associated with an *x*-monotone curve whose interior is disjoint from all other edges and vertices. Recall that an arrangement edge is always comprised of a pair of twin DCEL halfedges.

The *Arrangement_2<Traits,Dcel>* template has two parameters:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits_2* concept. The traits class defines the types of *x*-monotone curves and two-dimensional points, namely *X_monotone_curve_2* and *Point_2*, respectively, and supports basic geometric predicates on them.
- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is by default *Arr_default_dcel<Traits>*.

The available traits classes and DCEL classes are described below.

Self is an abbreviation of the *Arrangement_2<Traits,Dcel>* type hereafter.

```
#include <CGAL/Arrangement_2.h>
```

Types

<i>Arrangement_2<Traits,Dcel>:: Traits_2</i>	the traits class in use.
<i>Arrangement_2<Traits,Dcel>:: Dcel</i>	the DCEL representation of the arrangement.
<i>typedef Arrangement_2<Traits_2,Dcel></i>	<i>Self</i> ;
<i>typedef typename Traits_2::Point_2</i>	<i>Point_2</i> ; the point type, as defined by the traits class.
<i>typedef typename Traits_2::X_monotone_curve_2</i>	<i>X_monotone_curve_2</i> ; the <i>x</i> -monotone curve type, as defined by the traits class.
<i>typedef typename Dcel::Size</i>	<i>Size</i> ; the size type (equivalent to <i>size_t</i>).
<i>Arrangement_2<Traits,Dcel>:: Vertex</i>	represents a 0-dimensional cell in the subdivision. A vertex is always associated with a point.
<i>Arrangement_2<Traits,Dcel>:: Halfedge</i>	represents (together with its twin — see below) a 1-dimensional cell in the subdivision. A halfedge is always associated with an <i>x</i> -monotone curve.
<i>Arrangement_2<Traits,Dcel>:: Face</i>	represents a 2-dimensional cell in the subdivision.

The following handles, iterators, and circulators all have respective constant counterparts (for example, in addition to *Vertex_iterator* the type *Vertex_const_iterator* is also defined). See [MS96] for a discussion of constant versus mutable iterator types. The mutable types are assignable to their constant counterparts.

Vertex_iterator, *Halfedge_iterator*, and *Face_iterator* are equivalent to the respective handle types (namely, *Vertex_handle*, *Halfedge_handle*, and *Face_handle*). Thus, wherever the handles appear in function parameter lists, the respective iterators can be passed as well.

<i>Arrangement_2<Traits,Dcel>:: Vertex_handle</i>	a handle for an arrangement vertex.
<i>Arrangement_2<Traits,Dcel>:: Halfedge_handle</i>	a handle for a halfedge. The halfedge and its twin form together an arrangement edge.
<i>Arrangement_2<Traits,Dcel>:: Face_handle</i>	a handle for an arrangement face.
<i>Arrangement_2<Traits,Dcel>:: Vertex_iterator</i>	a bidirectional iterator over the vertices of the arrangement. Its value-type is <i>Vertex</i> .
<i>Arrangement_2<Traits,Dcel>:: Halfedge_iterator</i>	a bidirectional iterator over the halfedges of the arrangement. Its value-type is <i>Halfedge</i> .
<i>Arrangement_2<Traits,Dcel>:: Edge_iterator</i>	a bidirectional iterator over the edges of the arrangement. (That is, it skips every other halfedge.) Its value-type is <i>Halfedge</i> .
<i>Arrangement_2<Traits,Dcel>:: Face_iterator</i>	a bidirectional iterator over the faces of arrangement. Its value-type is <i>Face</i> .
<i>Arrangement_2<Traits,Dcel>:: Halfedge_around_vertex_circulator</i>	a bidirectional circulator over the halfedges that have a given vertex as their target. Its value-type is <i>Halfedge</i> .
<i>Arrangement_2<Traits,Dcel>:: Ccb_halfedge_circulator</i>	a bidirectional circulator over the halfedges of a CCB (connected component of the boundary). Its value-type is <i>Halfedge</i> . Each bounded face has a single CCB representing its outer boundary, and may have several inner CCBs representing its holes.
<i>Arrangement_2<Traits,Dcel>:: Hole_iterator</i>	a bidirectional iterator over the holes (i.e., inner CCBs) contained inside a given face. Its value type is <i>Ccb_halfedge_circulator</i> .
<i>Arrangement_2<Traits,Dcel>:: Isolated_vertex_iterator</i>	a bidirectional iterator over the isolated vertices contained inside a given face. Its value type is <i>Vertex</i> .

Creation

<i>Arrangement_2<Traits,Dcel> arr;</i>	constructs an empty arrangement containing one unbounded face, which corresponds to the entire plane.
<i>Arrangement_2<Traits,Dcel> arr(Self other);</i>	copy constructor.
<i>Arrangement_2<Traits,Dcel> arr(Traits_2 *traits);</i>	constructs an empty arrangement that uses the given <i>traits</i> instance for performing the geometric predicates.

Assignment Methods

<i>Self</i> &	<i>arr = other</i>	assignment operator.
<i>void</i>	<i>arr.assign(Self other)</i>	assigns the contents of another arrangement.
<i>void</i>	<i>arr.clear()</i>	clears the arrangement.

Access Functions

<i>Traits_2*</i>	<i>arr.get_traits()</i>	returns the traits object used by the arrangement instance. A <i>const</i> version is also available.
<i>bool</i>	<i>arr.is_empty()</i>	determines whether the arrangement is empty (contains only the unbounded face, with no vertices or edges).

All *_begin()* and *_end()* methods listed below also have *const* counterparts, returning constant iterators instead of mutable ones:

• Accessing the Arrangement Vertices:

<i>Size</i>	<i>arr.number_of_vertices()</i>	returns the number of vertices in the arrangement.
<i>Size</i>	<i>arr.number_of_isolated_vertices()</i>	returns the total number of isolated vertices in the arrangement.
<i>Vertex_iterator</i>	<i>arr.vertices_begin()</i>	returns the begin-iterator of the vertices in the arrangement.
<i>Vertex_iterator</i>	<i>arr.vertices_end()</i>	returns the past-the-end iterator of the vertices in the arrangement.

• Accessing the Arrangement Edges:

<i>Size</i>	<i>arr.number_of_halfedges()</i>	returns the number of halfedges in the arrangement.
<i>Halfedge_iterator</i>	<i>arr.halfedges_begin()</i>	returns the begin-iterator of the halfedges in the arrangement.
<i>Halfedge_iterator</i>	<i>arr.halfedges_end()</i>	returns the past-the-end iterator of the halfedges in the arrangement.
<i>Size</i>	<i>arr.number_of_edges()</i>	returns the number of edges in the arrangement (equivalent to <i>arr.number_of_halfedges() / 2</i>).
<i>Edge_iterator</i>	<i>arr.edges_begin()</i>	returns the begin-iterator of the edges in the arrangement.
<i>Edge_iterator</i>	<i>arr.edges_end()</i>	returns the past-the-end iterator of the edges in the arrangement.

- *Accessing the Arrangement Faces:*

<i>Face_handle</i>	<i>arr.unbounded_face()</i>	returns a handle for the unbounded face of the arrangement.
<i>Size</i>	<i>arr.number_of_faces()</i>	returns the number of faces in the arrangement.
<i>Face_iterator</i>	<i>arr.faces_begin()</i>	returns the begin-iterator of the faces in the arrangement.
<i>Face_iterator</i>	<i>arr.faces_end()</i>	returns the past-the-end iterator of the faces in the arrangement.

— *advanced* —

Casting away Constness

It is sometime necessary to convert a constant (non-mutable) handle to a mutable handle. For example, the result of a point-location query is a non-mutable handle for the arrangement cell containing the query point. Assume that the query point lies on a edge, so we obtain a *Halfedge_const_handle*; if we wish to use this handle and remove the edge, we first need to cast away its “constness”.

<i>Vertex_handle</i>	<i>arr.non_const_handle(Vertex_const_handle v)</i>	casts the given constant vertex handle to an equivalent mutable handle.
----------------------	-----------------------------------------------------	-------------------------------------------------------------------------

<i>Halfedge_handle</i>	<i>arr.non_const_handle(Halfedge_const_handle e)</i>	casts the given constant halfedge handle to an equivalent mutable handle.
------------------------	-------------------------------------------------------	---------------------------------------------------------------------------

<i>Face_handle</i>	<i>arr.non_const_handle(Halfedge_const_handle f)</i>	casts the given constant face handle to an equivalent mutable handle.
--------------------	-------------------------------------------------------	-----------------------------------------------------------------------

— *advanced* —

Modifiers

- *Specialized Insertion Methods:*

<i>Vertex_handle</i>	<i>arr.insert_in_face_interior(Point_2 p, Face_handle f)</i>	inserts the point <i>p</i> into the arrangement as an isolated vertex in the interior of the face <i>f</i> and returns a handle for the newly created vertex. <i>Precondition:</i> <i>p</i> lies in the interior of the face <i>f</i> .
----------------------	---------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Halfedge_handle *arr.insert_in_face_interior(X_monotone_curve_2 c, Face_handle f)*

inserts the curve *c* as a new hole (inner component) of the face *f*. As a result, two new vertices that correspond to *c*'s endpoints are created and connected with a newly created halfedge pair. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed in lexicographic increasing order (from left to right).
Precondition: *c* lies entirely in the interior of the face *f* and is disjoint from all existing arrangement vertices and edges (in particular, both its endpoints are not already associated with existing arrangement vertices).

Halfedge_handle *arr.insert_from_left_vertex(X_monotone_curve_2 c, Vertex_handle v)*

inserts the curve *c* into the arrangement, such that its left endpoint corresponds to a given arrangement vertex. As a result, a new vertex that correspond to *c*'s right endpoint is created and connected to *v* with a newly created halfedge pair. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed towards the newly created vertex — that is, directed in lexicographic increasing order (from left to right).
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.
Precondition: *v* is associated with the left endpoint of *c*.
Precondition: The right endpoint of *c* is not already associated with an existing arrangement vertex.

Halfedge_handle *arr.insert_from_right_vertex(X_monotone_curve_2 c, Vertex_handle v)*

inserts the curve *c* into the arrangement, such that its right endpoint corresponds to a given arrangement vertex. As a result, a new vertex that correspond to *c*'s left endpoint is created and connected to *v* with a newly created halfedge pair. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed to the newly created vertex — that is, directed in lexicographic decreasing order (from right to left).
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.
Precondition: *v* is associated with the right endpoint of *c*.
Precondition: The left endpoint of *c* is not already associated with an existing arrangement vertex.

```
Halfedge_handle arr.insert_at_vertices( X_monotone_curve_2 c, Vertex_handle v1, Vertex_handle v2)
```

inserts the curve c into the arrangement, such that both c 's endpoints correspond to existing arrangement vertices, given by $v1$ and $v2$. The function creates a new halfedge pair that connects the two vertices, and returns a handle for the halfedge directed from $v1$ to $v2$.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $v1$ and $v2$ are associated with c 's endpoints.

Precondition: If $v1$ and $v2$ are already connected by an edge, this edge represents an x -monotone curve that is interior-disjoint from c).

- *advanced*

```
Halfedge_handle arr.insert_from_left_vertex( X_monotone_curve_2 c, Halfedge_handle pred)
```

inserts the curve c into the arrangement, such that its left endpoint corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge $pred$, such that c is inserted to the circular list of halfedges around $pred \rightarrow target()$ right between $pred$ and its successor. The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred \rightarrow target()$ is associated with the left endpoint of c , and c should be inserted after $pred$ in a clockwise order around this vertex.

Precondition: The right endpoint of c is not already associated with an existing arrangement vertex.

```
Halfedge_handle arr.insert_from_right_vertex( X_monotone_curve_2 c, Halfedge_handle pred)
```

inserts the curve c into the arrangement, such that its right endpoint corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge $pred$, such that c is inserted to the circular list of halfedges around $pred \rightarrow target()$ right between $pred$ and its successor. The function returns a handle for one of the new halfedges directed (lexicographically) from right to left.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred \rightarrow target()$ is associated with the right endpoint of c , and c should be inserted after $pred$ in a clockwise order around this vertex.

Precondition: The left endpoint of c is not already associated with an existing arrangement vertex.

[illegible]

Vertex_handle v2)

inserts the curve c into the arrangement, such that both c 's endpoints correspond to existing arrangement vertices, given by $predI \rightarrow target()$ and $v2$. The function creates a new halfedge pair that connects the two vertices (where the corresponding halfedge is inserted right between $predI$ and its successor around $predI$'s target vertex) and returns a handle for the halfedge directed from $predI \rightarrow target()$ to $v2$.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred1 \rightarrow target()$ and $v2$ are associated with c 's endpoints.

Precondition: If $pred1 \rightarrow target$ and $v2$ are already connected by an edge, this edge represents an x -monotone curve that is interior-disjoint from c).

[illegible]

inserts the curve c into the arrangement, such that both c 's endpoints correspond to existing arrangement vertices, given by $pred1 \rightarrow target()$ and $pred2 \rightarrow target()$. The function creates a new halfedge pair that connects the two vertices (with $pred1$ and $pred2$ indicate the exact place for these halfedges around the two target vertices) and returns a handle for the halfedge directed from $pred1 \rightarrow target()$ to $pred2 \rightarrow target()$.

Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.

Precondition: $pred1 \rightarrow target()$ and $pred2 \rightarrow target()$ are associated with c 's endpoints.

Precondition: If $pred1 \rightarrow target$ and $pred2 \rightarrow target()$ are already connected by an edge, this edge represents an x -monotone curve that is interior-disjoint from c).

_____ *advanced* _____

- *Modifying Vertices and Edges:*

```
Vertex_handle      arr.modify_vertex( Vertex_handle v, Point_2 p)
```

sets p to be the point associated with the vertex v . The function returns a handle for the modified vertex (same as v).

Precondition: p is geometrically equivalent to the point currently associated with γ .

bool remove_target = true)

removes the edge e from the arrangement. Since the e may be the only edge incident to its source vertex (or its target vertex), this vertex can be removed as well. The flags *remove_source* and *remove_target* indicate whether the endpoints of e should be removed, or whether they should be left as isolated vertices in the arrangement. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

Miscellaneous

bool *arr.is_valid()*

returns *true* if *arr* represents a valid instance of *Arrangement_2<Traits,Dcel>*. In particular, the function checks the topological structure of the arrangement and assures that it is valid. In addition, the function performs several simple geometric tests to ensure the validity of some of the geometric properties of the arrangement. Namely, it checks that all arrangement vertices are associated with distinct points, and that the halfedges around every vertex are ordered clockwise.

CGAL::Arr_accessor<Arrangement>

Definition

Arr_accessor<*Arrangement*> provides an access to some of the private *Arrangement* functions. Users may use these functions to achieve more efficient programs when they have the exact topological information required by the specialized functions.

It is however highly recommended to be very careful when using the accessor functions that modify the arrangement. As we have just mentioned, these functions have very specific requirement on their input on one hand, and perform no preconditions on the other hand, so providing incorrect topological input may invalidate the arrangement.

```
#include <CGAL/Arr_accessor.h>
```

Types

Arr_accessor<*Arrangement*>::*Arrangement_2* the type of the associated arrangement.

```
typedef typename Arrangement_2::Point_2
```

```
Point_2;                    the point type.
```

```
typedef typename Arrangement_2::X_monotone_curve_2
```

```
X_monotone_curve_2;
```

the *x*-monotone curve type.

```
typedef typename Arrangement_2::Vertex_handle
```

```
Vertex_handle;
```

```
typedef typename Arrangement_2::Halfedge_handle
```

```
Halfedge_handle;
```

```
typedef typename Arrangement_2::Face_handle
```

```
Face_handle;
```

```
typedef typename Arrangement_2::Ccb_halfedge_circulator
```

```
Ccb_halfedge_circulator;
```

represents the boundary of a connected component (CCB).

Creation

```
Arr_accessor<Arrangement> acc( Arrangement_2& arr);
```

constructs an accessor attached to the given arrangement *arr*.

Accessing the notification functions

void *acc.notify_before_global_change()*

notifies the arrangement observer that a global change is going to take place (for the usage of the global functions that operate on arrangements).

void *acc.notify_after_global_change()*

notifies the arrangement observer that a global change has taken place (for the usage of the global functions that operate on arrangements).

— *advanced* —

Arrangement Predicates

Halfedge_handle *acc.locate_around_vertex(Vertex_handle v, X_monotone_curve_2 c)*

locates a place for the curve *c* around the vertex *v* and returns a halfedge whose target is *v*, where *c* should be inserted between this halfedge and the next halfedge around *v* in a clockwise order.

int *acc.halfedge_distance(Halfedge_const_handle e1, Halfedge_const_handle e2)*

counts the number of edges along the path from *e1* to *e2*. In case the two halfedges do not belong to the same connected component, the function returns (-1).

bool *acc.is_inside_new_face(Halfedge_handle pred1, Halfedge_handle pred2, X_monotone_curve_2 c)*

determines whether a new halfedge we are about to create, which is to be associated with the curve *c* and directed from *pred1*->*target()* to *pred2*->*target()*, lies on the inner CCB of the new face that will be created, introducing this new edge.
Precondition: *pred1*->*target()* and *pred2*->*target()* are associated with *c*'s endpoints.
Precondition: *pred1* and *pred2* belong to the same connected component, such that a new face is created by connecting *pred1*->*target()* and *pred2*->*target()*.

bool *acc.point_is_in(Point_2 p, Halfedge_const_handle he)*

determines whether a given point lies within the region bounded by a boundary of the connected component that *he* belongs to. Note that if the function returns *true*, then *p* is contained within *he*->*face()* (but not on its boundary), or inside one of the holes inside this face, or it may coincide with an isolated vertex in this face.

<i>Halfedge_handle</i>	<code>acc.insert_at_vertices_ex(X_monotone_curve_2 c, Halfedge_handle pred1, Halfedge_handle pred2, Comparison_result res, bool& new_face)</code> <p>inserts the curve <i>c</i> into the arrangement, such that both <i>c</i>'s endpoints correspond to existing arrangement vertices, given by <i>pred1</i>-><i>target()</i> and <i>pred2</i>-><i>target()</i>. <i>res</i> is the comparison result between these two end-vertices. The function creates a new halfedge pair that connects the two vertices (with <i>pred1</i> and <i>pred2</i> indicate the exact place for these halfedges around the two target vertices) and returns a handle for the halfedge directed from <i>pred1</i>-><i>target()</i> to <i>pred2</i>-><i>target()</i>. The output flag <i>new_face</i> indicates whether a new face has been created following the insertion of the new curve. <i>Precondition:</i> It is the user's responsibility that <i>pred1</i>-><i>target()</i> and <i>pred2</i>-><i>target()</i> are associated with <i>c</i>'s endpoints and that if a new face is created, then <i>is_inside_new_face</i> (<i>pred1</i>, <i>pred2</i>, <i>c</i>) is <i>true</i>.</p>
<i>void</i>	<code>acc.insert_isolated_vertex(Face_handle f, Vertex_handle v)</code> <p>inserts <i>v</i> as an isolated vertex inside <i>f</i>. <i>Precondition:</i> It is the user's responsibility that <i>v</i>-><i>point()</i> is contained in the interior of the given face.</p>
<i>void</i>	<code>acc.move_hole(Face_handle f1, Face_handle f2, Ccb_halfedge_circulator hole)</code> <p>moves the given hole from the interior of the face <i>f1</i> inside the face <i>f2</i>. <i>Precondition:</i> It is the user's responsibility that <i>hole</i> is currently contained in <i>f1</i> and should be moved to <i>f2</i>.</p>
<i>bool</i>	<code>acc.move_isolated_vertex(Face_handle f1, Face_handle f2, Vertex_handle v)</code> <p>moves the given isolated vertex from the interior of the face <i>f1</i> inside the face <i>f2</i>. <i>Precondition:</i> It is the user's responsibility that <i>v</i> is indeed an isolated vertex currently contained in <i>f1</i> and should be moved to <i>f2</i>.</p>
<i>void</i>	<code>acc.relocate_in_new_face(Halfedge_handle he)</code> <p>relocates all holes and isolated vertices to their proper position immediately after a face has split due to the insertion of a new halfedge, namely after <i>insert_at_vertices_ex()</i> was invoked and indicated that a new face has been created. <i>he</i> is the halfedge returned by <i>insert_at_vertices_ex()</i>, such that <i>he</i>-><i>twin()</i>-><i>face</i> is the face that has just been split and <i>he</i>-><i>face()</i> is the newly created face.</p>

<i>void</i>	<i>acc.relocate_holes_in_new_face(Halfedge_handle he)</i>	relocates all holes in a new face, as detailed above.
<i>void</i>	<i>acc.relocate_isolated_vertices_in_new_face(Halfedge_handle he)</i>	relocates all isolated vertices in a new face, as detailed above.
<i>Vertex_handle</i>	<i>acc.modify_vertex_ex(Vertex_handle v, Point_2 p)</i>	<p>modifies the point associated with the vertex v (the point may be geometrically different than the one currently associated with v). The function returns a handle to the modified vertex (same as v).</p> <p><i>Precondition:</i> It is the user's responsibility that no other arrangement vertex is already associated with p.</p>
<i>Halfedge_handle</i>	<i>acc.modify_edge_ex(Halfedge_handle e, X_monotone_curve_2 c)</i>	<p>modifies the x-monotone curve associated with the edge e (the curve c may be geometrically different than the one currently associated with e). The function returns a handle to the modified edge (same as e).</p> <p><i>Precondition:</i> It is the user's responsibility that the interior of c is disjoint from all existing arrangement vertices and edges.</p>
<i>Halfedge_handle</i>	<i>acc.split_edge_ex(Halfedge_handle he, Point_2 p, X_monotone_curve_2 c1, X_monotone_curve_2 c2)</i>	<p>splits a given edge into two at the split point p, and associate the x-monotone curves $c1$ and $c2$ with the resulting edges, such that $c1$ connects $he \rightarrow source()$ with p and $c2$ connects p with $he \rightarrow target()$. The function return a handle to the split halfedge directed from $he \rightarrow source()$ to the split point p.</p> <p><i>Precondition:</i> It is the user's responsibility that the endpoints of $c1$ and $c2$ correspond to p and to he's end-vertices, as indicated above.</p>
<i>Halfedge_handle</i>	<i>acc.split_edge_ex(Halfedge_handle he, Vertex_handle v, X_monotone_curve_2 c1, X_monotone_curve_2 c2)</i>	<p>splits a given edge into two at by the vertex v, and associate the x-monotone curves $c1$ and $c2$ with the resulting edges, such that $c1$ connects $he \rightarrow source()$ with v and $c2$ connects v with $he \rightarrow target()$. The function return a handle to the split halfedge directed from $he \rightarrow source()$ to v.</p> <p><i>Precondition:</i> It is the user's responsibility that the endpoints of $c1$ and $c2$ correspond to v and to he's end-vertices, as indicated above. It is also assumed that v has no incident edges.</p>

Face_handle

```
acc.remove_edge_ex( Halfedge_handle he,  
bool remove_source = true,  
bool remove_target = true)
```

removes the edge *he* from the arrangement, such that if the edge removal causes the creation of a new hole, *he->target()* lies on the boundary of this hole. The flags *remove_source* and *remove_target* indicate whether the end-vertices of *he* should be removed as well, in case they have no other incident edges. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

└────────── *advanced* ─────────┘

CGAL::Arrangement_2<Traits,Dcel>::Vertex

Definition

An object v of the class *Vertex* represents an arrangement vertex, that is — a 0-dimensional cell, associated with a point on the plane.

Inherits From

typename Dcel::Vertex

Creation

<i>Vertex</i> <i>v</i> ;	default constructor.
--------------------------	----------------------

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

<i>bool</i>	<i>v.is_isolated()</i>	checks whether the vertex is isolated. (It has no incident edges.)
-------------	------------------------	--------------------------------------------------------------------

<i>typename Dcel::Size</i>	<i>v.degree()</i>	returns the number of edges incident to <i>v</i> .
----------------------------	-------------------	----------------------------------------------------

<i>Halfedge_around_vertex_circulator</i>	<i>v.incident_halfedges()</i>
------------------------------------------	-------------------------------

returns a circulator circulator that allows going over the halfedges incident to v (that have v as their target). The edges are traversed in a clockwise direction around v .

Precondition: v is *not* an isolated vertex.

<i>Face_handle</i>	<i>v.face()</i>	returns a handle to the face that contains <i>v</i> in its interior.
--------------------	-----------------	----------------------------------------------------------------------

Precondition: v is an isolated vertex.

<i>typename Traits::Point_2</i>	<i>v.point()</i>	returns the point associated with the vertex.
---------------------------------	------------------	-----------------------------------------------

CGAL::Arrangement_2<Traits,Dcel>::Face

Definition

An object e of the class *Face* represents an arrangement edge, namely a 2-dimensional arrangement cell. Every arrangement contains exactly one *unbounded* face, an a number of bounded face. Each bounded face has a boundary comprised of a halfedge chain winding in a counterclockwise orientation around it. A face may also contain holes, which are defined by clockwise-oriented halfedge chains, and isolated vertices.

Inherits From

typename Dcel::Face

Creation

<i>Face</i> <i>f</i> ;	default constructor.
------------------------	----------------------

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

<i>bool</i>	<i>f.is_unbounded()</i>	returns whether the face is unbounded.
-------------	-------------------------	----------------------------------------

Ccb_halfedge_circulator

f.outer_ccb() returns a circulator that allows going over the outer boundary of *f*. The edges along the CCB are traversed in a counter-clockwise direction.
Precondition: *f* is not an unbounded face.

<i>Hole_iterator</i>	<i>f.holes_begin()</i>	returns an iterator for traversing all the holes (inner CCBs) of <i>f</i> .
----------------------	------------------------	-----------------------------------------------------------------------------

<i>Hole_iterator</i>	<i>f.holes_end()</i>	returns a past-the-end iterator for the holes of <i>f</i> .
----------------------	----------------------	-------------------------------------------------------------

Isolated_vertex_iterator

`f.isolated_vertices_begin()`

returns an iterator for traversing all the isolated vertices contained in the interior of f .

Isolated_vertex_iterator

`f.isolated_vertices_end()`

returns a past-the-end iterator for the isolated vertices contained inside `f`.

CGAL::is_valid

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel>
```

```
bool is_valid( Arrangement_2<Traits, Dcel> arr)
```

Checks the validity of the given arrangement. It first invokes the member function *arr.is_valid()* to ensure the topological correctness of the arrangement. Then it performs additional validity tests. First, it checks that all *x*-monotone curves associated with arrangement edges are pairwise disjoint in their interior. Then it makes sure that all holes and all isolated vertices are located within the proper arrangement faces. The traits class in use must be a model of the concept *ArrangementXMonotoneTraits_2*. Note that the test carried out by this functions may take a considerable amount of time; it should therefore be used only for debugging purposes.

CGAL::insert_curve

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, class PointLocation>
void insert_curve( Arrangement_2<Traits,Dcel>& arr,
                  typename Traits::Curve_2 c,
                  PointLocation pl = walk_pl)
```

Inserts the given curve c into the arrangement arr , where no restrictions are made on the nature of the inserted curve. The *Traits* parameter must be a model of the *ArrangementTraits_2* concept. That is, it should define the *Curve_2* type and support its subdivision into x -monotone subcurves (and perhaps isolated points). Each subcurve is in turn inserted into the arrangement by locating its left endpoint and computing its zone until reaching the right endpoint. The point-location object pl , which must be a model of the *ArrangementPointLocation_2* concept, is used for answering point-location queries during the insertion process. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_2*<*Traits*,*Dcel*>>.

Precondition: If provided, pl must be attached to the given arrangement arr .

```
#include <CGAL/Arrangement_with_history_2.h>
```

```
template<class Traits, class Dcel, class PointLocation>
typename Arrangement_with_history_2<Traits,Dcel>::Curve_handle
insert_curve( Arrangement_with_history_2<Traits,Dcel>& arr,
              typename Traits::Curve_2 c,
              PointLocation pl = walk_pl)
```

Inserts the given curve c into the arrangement arr , and returns a handle to the inserted curve. The point-location object pl , which should be a model of the *ArrangementPointLocation_2* concept, is used for answering point-location queries during the insertion process. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*<*Arrangement_with_history_2*<*Traits*,*Dcel*>>.

Precondition: If provided, pl is attached to the given arrangement arr .

CGAL::insert_curves

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, InputIterator>
void          insert_curves( Arrangement_2<Traits,Dcel>& arr,
                           InputIterator first,
                           InputIterator last)
```

Aggregately inserts the given range of curves $[first, last)$ into the arrangement *arr*, where no restrictions are made on the nature of the inserted curves. The *Traits* parameter must be a model of the *ArrangementTraits_2* concept. The input curves are subdivided into *x*-monotone subcurves (and perhaps isolated points), which are inserted into the arrangement using the sweep-line algorithm.

Precondition: The value-type of *InputIterator* is *Traits::Curve_2*.

```
#include <CGAL/Arrangement_with_history_2.h>
```

```
template<class Traits, class Dcel, InputIterator>
void          insert_curves( Arrangement_with_history_2<Traits,Dcel>& arr,
                           InputIterator first,
                           InputIterator last)
```

Aggregately inserts the given range of curves $[first, last)$ into the arrangement *arr*.

Precondition: The value-type of *InputIterator* is *Traits::Curve_2*.

CGAL::insert_x_monotone_curve

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, class PointLocation>
void insert_x_monotone_curve( Arrangement_2<Traits,Dcel>& arr,
                             typename Traits::X_monotone_curve_2 xc,
                             PointLocation pl = walk_pl)
```

Inserts the given x -monotone curve xc into the arrangement arr . The *Traits* parameter must be a model of the *ArrangementXMonotoneTraits_2* concept. xc is inserted into the arrangement by locating its left endpoint and computing its zone until reaching the right endpoint. The point-location object pl , which must be a model of the *ArrangementPointLocation_2* concept, is used for locating the left endpoint of xc in the existing arrangement. By default, the function uses the “walk along line” point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel>>*.

Precondition: If provided, pl must be attached to the given arrangement arr .

```
template<class Traits, class Dcel>
void insert_x_monotone_curve( Arrangement_2<Traits,Dcel>& arr,
                             typename Traits::X_monotone_curve_2 xc,
                             Object obj)
```

Inserts the given x -monotone curve xc into the arrangement arr . The *Traits* parameter must be a model of the *ArrangementXMonotoneTraits_2* concept. The object obj , which either wraps a *Vertex_const_handle*, a *Halfedge_const_handle* or a *Face_const_handle*, represents the location of xc ’s left endpoint in the arrangement. xc is thus inserted into the arrangement from the feature represented by obj by computing its zone until reaching the right endpoint (no point-location query is issued).

CGAL::insert_x_monotone_curves

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, InputIterator>  
void          insert_x_monotone_curves( Arrangement_2<Traits,Dcel>& arr,  
                                       InputIterator first,  
                                       InputIterator last)
```

Inserts the given range of x -monotone curves $[first, last)$ into the arrangement arr . The insertion is performed in an aggregated manner, using the sweep-line algorithm. The *Traits* parameter must be a model of the *ArrangementXMonotoneTraits_2* concept.

Precondition: The value-type of *InputIterator* is *Traits::X_monotone_curve_2*.

CGAL::insert_non_intersecting_curve

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, class PointLocation>
typename Arrangement_2<Traits,Dcel>::Halfedge_handle
```

```
insert_non_intersecting_curve( Arrangement_2<Traits,Dcel>& arr,
                               typename Traits::X_monotone_curve_2 xc,
                               PointLocation pl = walk_pl)
```

inserts the given x -monotone curve xc into the arrangement arr , where the interior of xc is disjoint from all existing arrangement vertices and edges. Under this assumption, it is possible to locate the endpoints of xc in the arrangement and use one of the specialized insertion member-functions of arr according to the results. As no intersection are computed, the *Traits* parameter must model the restricted *ArrangementBasicTraits_2* concept. The point-location object pl , which must model the *ArrangementPointLocation_2* concept, is used for answering the two point-location queries on xc 's endpoints. The insertion operation creates a single new edge, that is, two twin halfedges, and the function returns a handle for the one directed lexicographically in increasing order (from left to right). By default, the function uses the “walk along line” point-location strategy — namely, an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel>>*.

Precondition: If provided, pl must be attached to the given arrangement arr .

CGAL::insert_non_intersecting_curves

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, InputIterator>  
void          insert_non_intersecting_curves( Arrangement_2<Traits,Dcel>& arr,  
                                              InputIterator first,  
                                              InputIterator last)
```

Aggregately inserts the given range of x -monotone curves $[first, last)$ into the arrangement arr . The input curves should be pairwise disjoint in their interior and pairwise interior-disjoint from all existing arrangement vertices and edges. The *Traits* parameter must be a model of the *ArrangementBasicTraits_2* concept.

Precondition: The value-type of *InputIterator* is *Traits::X_monotone_curve_2*.

CGAL::insert_point

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel, class PointLocation>
```

```
typename Arrangement_2<Traits,Dcel>::Vertex_handle
```

```
insert_point( Arrangement_2<Traits,Dcel>& arr,
              typename Traits::Point_2 p,
              PointLocation pl = walk_pl)
```

inserts the point p as an arrangement vertex into arr . The function uses the point-location object pl (a model of the *ArrangementPointLocation_2* concept) to locate p in arr . If it coincides with an existing vertex, there is nothing left to do; if it lies on an edge, the edge is split at p ; otherwise, p is contained inside a face, and is inserted as an isolated vertex inside this face. At any case, the function returns a handle for the vertex associated with p . The *Triats* parameter must model the refined concept *ArrangementXMonotoneTraits_2*, which requires split operations. By default, the function uses the “walk along line” point-location strategy — namely, an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*.

Precondition: If provided, pl must be attached to the given arrangement arr .

CGAL::remove_edge

```
#include <CGAL/Arrangement_2.h>
```

```
template<class Traits, class Dcel>
```

```
typename Arrangement_2<Traits,Dcel>::Face_handle
```

```
remove_edge( Arrangement_2<Traits,Dcel>& arr,  
             typename Arrangement_2<Traits,Dcel>::Halfedge_handle e)
```

removes an edge given by one of the twin halfedges e that forms it, from the arrangement arr . Using this function is equivalent to invoking `arr.remove_edge(e , $true$, $true$)` — that is, to remove the edge and its end-vertices, in case they become isolated. However, this free function requires that $Traits$ be a model of the refined concept *ArrangementXMonotoneTraits_2*, which requires merge operations on x -monotone curves. If one of the end-vertices of e becomes redundant after e is removed (see `remove_vertex()` for the definition of a redundant vertex), it is removed and its incident edges are merged. If the edge-removal operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

CGAL::remove_vertex

```
#include <CGAL/Arrangement_2.h>
```

```
template <class Traits, class Dcel>
```

```
bool remove_vertex( Arrangement_2<Traits,Dcel>& arr,  
                   typename Arrangement_2<Traits,Dcel>::Vertex_handle v)
```

Tries to removed the vertex v from the given arrangement arr . The vertex can be removed if it is either an isolated vertex and has no incident edge, or if it is a *redundant* vertex — that is, it has exactly two incident edges whose associated curves can be merged to form a single x -monotone curve. The assumption is that *Traits* is a model of the refines *ArrangementXMonotoneTraits_2*, such that it supports merge operations on x -monotone curves. The function returns whether it succeeded in deleting v from the arrangement.

CGAL::overlay

```
#include <CGAL/Arr_overlay.h>
```

```
template<class Traits, class Dcel1, class Dcel2, class RedDcel, class OverlayTraits>
void overlay( Arrangement_2<Traits,Dcel1> arr1,
              Arrangement_2<Traits,Dcel2> arr2,
              Arrangement_2<Traits,ResDcel>& res,
              OverlayTraits ovl_tr)
```

Computes the overlay of two input arrangement instances *arr1* and *arr2* and sets the output arrangement *res* to represent the overlaid arrangement. All three arrangements are instantiated using the same geometric traits class, but may be represented using different DCEL classes. In order to properly construct the overlaid DCEL that represents *res*, the function uses the overlay-traits object *ovl_tr*, which should be a model of the *OverlayTraits* concept, which is able to construct records of the *ResDcel* class on the basis of the *Dcel1* and *Dcel2* records that induce them.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

```
#include <CGAL/Arrangement_with_history_2.h>
```

```
template<class Traits, class Dcel1, class Dcel2, class RedDcel, class OverlayTraits>
void overlay( Arrangement_with_history_2<Traits,Dcel1> arr1,
              Arrangement_with_history_2<Traits,Dcel2> arr2,
              Arrangement_2<Traits,ResDcel>& res,
              OverlayTraits ovl_tr)
```

Computes the overlay of two input arrangement-with-history instances *arr1* and *arr2* and sets the output arrangement *res* to represent the overlaid arrangement. All three arrangements are instantiated using the same geometric traits class, but may be represented using different DCEL classes. In order to properly construct the overlaid DCEL that represents *res*, the function uses the overlay-traits object *ovl_tr*, which should be a model of the *OverlayTraits* concept, which is able to construct records of the *ResDcel* class on the basis of the *Dcel1* and *Dcel2* records that induce them. The function also constructs a consolidated set of curves that induce *res*.

OverlayTraits(page [1230](#))

OverlayTraits

A model for the OverlayTraits should be able to operate on records (namely, vertices, halfedges and faces) of two input DCEL classes, named *Dcel_A* and *Dcel_B*, and construct the records of an output DCEL class, referred to as *Dcel_R*.

Models for the concept are used by the global *overlay()* function to maintain the auxiliary data stored with the DCEL records of the resulting overlaid arrangement, based on the contents of the input records.

Types

<i>OverlayTraits:: Vertex_handle_A</i>	a constant handle a vertex in <i>Dcel_A</i> .
<i>OverlayTraits:: Halfedge_handle_A</i>	a constant handle to a halfedge in <i>Dcel_A</i> .
<i>OverlayTraits:: Face_handle_A</i>	a constant handle to a face <i>Dcel_A</i> .
<i>OverlayTraits:: Vertex_handle_B</i>	a constant handle to a vertex in <i>Dcel_B</i> .
<i>OverlayTraits:: Halfedge_handle_B</i>	a constant handle to a halfedge in <i>Dcel_B</i> .
<i>OverlayTraits:: Face_handle_B</i>	a constant handle to a face in <i>Dcel_B</i> .
<i>OverlayTraits:: Vertex_handle_R</i>	a handle to a vertex in <i>Dcel_R</i> .
<i>OverlayTraits:: Halfedge_handle_R</i>	a handle to a halfedge in <i>Dcel_R</i> .
<i>OverlayTraits:: Face_handle_R</i>	a handle to a faces in <i>Dcel_R</i> .

Functions

Whenever a vertex in the overlaid arrangement is created, one of the following functions is called in order to attach the appropriate auxiliary data to this vertex:

<i>void</i>	<i>ovl_tr.create_vertex(Vertex_handle_A v1, Vertex_handle_B v2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the coinciding vertices <i>v1</i> and <i>v2</i> .
<i>void</i>	<i>ovl_tr.create_vertex(Vertex_handle_A v1, Halfedge_handle_B e2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the vertex <i>v1</i> that lies on the halfedge <i>e2</i> .
<i>void</i>	<i>ovl_tr.create_vertex(Vertex_handle_A v1, Face_handle_B f2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the vertex <i>v1</i> that lies inside the face <i>f2</i> .
<i>void</i>	<i>ovl_tr.create_vertex(Halfedge_handle_A e1, Vertex_handle_B v2, Vertex_handle_R v)</i>	constructs the vertex <i>v</i> induced by the vertex <i>v2</i> that lies on the halfedge <i>e1</i> .

void *ovl_tr.create_vertex(Face_handle_A f1, Vertex_handle_B v2, Vertex_handle_R v)*

constructs the vertex v induced by the vertex $v2$ that lies inside the face $f1$.

void *ovl_tr.create_vertex(Halfedge_handle_A e1, Halfedge_handle_B e2, Vertex_handle_R v)*

constructs the vertex v induced by the intersection of the halfedges $e1$ and $e2$.

Whenever an edge in the overlaid arrangement is created, one of the following functions is called in order to attach the appropriate auxiliary data to this vertex. Note that an edge is created after both its end-vertices are created, (and the corresponding *create_vertex()* methods were invoked). In all cases, the edge is represented by a halfedge e directed in lexicographic decreasing order (from right to left). The *create_edge()* method should attach auxiliary data to the twin halfedge (namely to $e \rightarrow \text{twin}()$) as well:

void *ovl_tr.create_edge(Halfedge_handle_A e1, Halfedge_handle_B e2, Halfedge_handle_R e)*

constructs the halfedge e induced by an overlap between the halfedges $e1$ and $e2$.

void *ovl_tr.create_edge(Halfedge_handle_A e1, Face_handle_B f2, Halfedge_handle_R e)*

constructs the halfedge e induced by the halfedge $e1$ that lies inside the face $f2$.

void *ovl_tr.create_edge(Face_handle_A f1, Halfedge_handle_B e2, Halfedge_handle_R e)*

constructs the halfedge e induced by the halfedge $e2$ that lies inside the face $f1$.

The following function is invoked whenever a new face is created. It is guaranteed that all halfedges along the face boundary have already been created and have their auxiliary data fields attached to them:

void *ovl_tr.create_face(Face_handle_A f1, Face_handle_B f2, Face_handle_R f)*

constructs the face f induced by the an overlap between the faces $f1$ and $f2$.

overlay (page [1229](#))

CGAL::Arr_face_overlay_traits<Arr_A,Arr_B,Arr_R,OvlFaceData>

Definition

An instance of *Arr_face_overlay_traits*<Arr_A,Arr_B,Arr_R,OvlFaceData> should be used for overlaying two arrangements of types Arr_A and Arr_B, which are instantiated using the same geometric traits-class and with the DCEL classes *Dcel_A* and *Dcel_B* respectively, in order to store their overlay in an arrangement of type Arr_R, which is instantiated using a third DCEL class *Dcel_R*. All three DCEL classes are assumed to be instantiations of the *Arr_face_extended_dcel* template with types *FaceData_A*, *FaceData_B* and *FaceData_R*, respectively.

This class gives empty implementation for all overlay traits-class functions, except the function that computes the overlay of two faces. In this case, it uses the functor *OvlFaceData*, which accepts a *FaceData_A* object and a *FaceData_B* object and computes a corresponding *FaceData_R* object, in order to set the auxiliary data of the overlay face.

read(page [1234](#))

ArrangementDcel

A doubly-connected edge-list (DCEL for short) data-structure. It consists of three containers of records: vertices V , halfedges E , and faces F . It maintains the incidence relation among them. The halfedges are ordered in pairs sometimes referred to as twins, such that each halfedge pair represent an edge.

A model of the ArrangementDcel concept must provide the following types and operations. (In addition to the requirements here, the local types *Vertex*, *Halfedge*, *Face* *Hole* and *Isolated_vertex* must be models of the concepts *ArrangementDcelVertex* (page 1239), *ArrangementDcelHalfedge* (page 1241), *ArrangementDcelFace* (page 1244), *ArrangementDcelHole* (page 1246) and *ArrangementDcelIsolatedVertex* (page 1247) respectively.)

Types

<i>ArrangementDcel:: Vertex</i>	the vertex type.
<i>ArrangementDcel:: Halfedge</i>	the halfedge type.
<i>ArrangementDcel:: Face</i>	the face type.
<i>ArrangementDcel:: Hole</i>	the hole type.
<i>ArrangementDcel:: Isolated_vertex</i>	the isolated vertex type.
<i>ArrangementDcel:: Size</i>	used to represent size values (e.g., <i>size_t</i>).
<i>ArrangementDcel:: Vertex_iterator</i>	a bidirectional iterator over the vertices. Its value-type is <i>Vertex</i> .
<i>ArrangementDcel:: Halfedge_iterator</i>	a bidirectional iterator over the halfedges. Its value-type is <i>Halfedge</i> .
<i>ArrangementDcel:: Face_iterator</i>	a bidirectional iterator over the faces. Its value-type is <i>Face</i> .

The non-mutable iterators *Vertex_const_iterator*, *Halfedge_const_iterator* and *Face_const_iterator* are also defined.

Creation

<i>ArrangementDcel dcel;</i>	constructs an empty DCEL with one unbounded face.
<i>Face*</i> <i>dcel.assign(Self other, const Face *uf)</i>	assigns the contents of the <i>other</i> DCEL whose unbounded face is given by <i>uf</i> , to <i>dcel</i> . The function returns a pointer to the unbounded face of <i>dcel</i> after the assignment.

Access Functions

<i>Size</i>	<i>dcel.size_of_vertices()</i>	returns the number of vertices.
<i>Size</i>	<i>dcel.size_of_halfedges()</i>	returns the number of halfedges (always even).
<i>Size</i>	<i>dcel.size_of_faces()</i>	returns the number of faces.

<i>Size</i>	<i>dcel.size_of_holes()</i>	returns the number of holes (the number of connected components).
<i>Size</i>	<i>dcel.size_of_isolated_vertices()</i>	returns the number of isolated vertices.

The following operations have an equivalent *const* operations that return the corresponding non-mutable iterators:

<i>Vertex_iterator</i>	<i>dcel.vertices_begin()</i>	returns a begin-iterator of the vertices in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.vertices_end()</i>	returns a past-the-end iterator of the vertices in <i>dcel</i> .
<i>Halfedge_iterator</i>	<i>dcel.halfedges_begin()</i>	returns a begin-iterator of the halfedges in <i>dcel</i> .
<i>Halfedge_iterator</i>	<i>dcel.halfedges_end()</i>	returns a past-the-end iterator of the halfedges in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.faces_begin()</i>	returns a begin-iterator of the faces in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.faces_end()</i>	returns a past-the-end iterator of the faces in <i>dcel</i> .

Modifiers

The following operations allocate a new element of the respective type. Halfedges are always allocated in pairs of opposite halfedges. The and their opposite pointers are automatically set.

<i>Vertex*</i>	<i>dcel.new_vertex()</i>	creates a new vertex.
<i>Halfedge*</i>	<i>dcel.new_edge()</i>	creates a new pair of twin halfedges.
<i>Face*</i>	<i>dcel.new_face()</i>	creates a new face.
<i>Hole*</i>	<i>dcel.new_hole()</i>	creates a new hole record.
<i>Isolated_vertex*</i>	<i>dcel.new_isolated_vertex()</i>	creates a new isolated vertex record.
<i>void</i>	<i>dcel.delete_vertex(Vertex* v)</i>	deletes the vertex <i>v</i> .
<i>void</i>	<i>dcel.delete_edge(Halfedge* e)</i>	deletes the halfedge <i>e</i> as well as its twin.
<i>void</i>	<i>dcel.delete_face(Face* f)</i>	deletes the face <i>f</i> .
<i>void</i>	<i>dcel.delete_hole(Hole* ho)</i>	deletes the hole <i>ho</i> .
<i>void</i>	<i>dcel.delete_isolated_vertex(Isolated_vertex* iv)</i>	deletes the isolated vertex <i>iv</i> .

ArrangementDcelIsolatedVertex (page [1247](#))

ArrangementDcelVertex

Definition

A vertex record in a DCEL data structure. A vertex is always associated with a point. However, the vertex record only stores a pointer to the associated point, and the actual *Point* object is stored elsewhere.

A vertex usually has several halfedges incident to it, such that it is possible to access one of these halfedges directly and to traverse all incident halfedges around the vertex. However, the DCEL may also contain isolated vertices that have no incident halfedges. In this case, the vertex stores an isolated vertex-information record, indicating the face that contains this vertex in its interior.

Types

<i>ArrangementDcelVertex::Halfedge</i>	the corresponding DCEL halfedge type.
<i>ArrangementDcelVertex::Isolated_vertex</i>	the corresponding DCEL isolated vertex-information type.
<i>ArrangementDcelVertex::Point</i>	the point type associated with the vertex.

Creation

<i>ArrangementDcelVertex</i> <i>v</i> ;	default constructor.
<i>void</i> <i>v.assign(Self other)</i>	assigns <i>v</i> with the contents of the <i>other</i> vertex.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or references:

<i>bool</i> <i>v.is_isolated()</i>	returns whether the vertex is isolated (has no incident halfedges).
<i>Halfedge*</i> <i>v.halfedge()</i>	returns an incident halfedge that has <i>v</i> as its target. <i>Precondition:</i> <i>v</i> is <i>not</i> an isolated vertex.
<i>Isolated_vertex*</i> <i>v.isolated_vertex()</i>	returns the isolated vertex-information record. <i>Precondition:</i> <i>v</i> is an isolated vertex.
<i>Point&</i> <i>v.point()</i>	returns the associated point.

Modifiers

<i>void</i> <i>v.set_halfedge(Halfedge* e)</i>	sets the incident halfedge, marking <i>v</i> as a regular vertex.
-------------------------------------------------	-------------------------------------------------------------------

void *v.set_isolated_vertex(Isolated_vertex* iv)*

sets the isolated vertex-information record, marking *v* as an isolated vertex.

void *v.set_point(Point* p)* sets the associated point.

ArrangementDcelHalfedge

Definition

A halfedge record in a DCEL data structure. Two halfedges with opposite directions always form an edge (a halfedge pair). The halfedges form together chains, defining the boundaries of connected components, such that all halfedges along a chain have the same incident face. Note that the chain the halfedge belongs to may form the outer boundary of a bounded face (an outer CCB) or the boundary of a hole inside a face (an inner CCB).

An edge is always associated with a curve, but the halfedge records only store a pointer to the associated curve, and the actual curve objects are stored elsewhere. Two opposite halfedges are always associated with the same curve.

Types

<i>ArrangementDcelHalfedge::Vertex</i>	the corresponding DCEL halfedge type.
<i>ArrangementDcelHalfedge::Face</i>	the corresponding DCEL face type.
<i>ArrangementDcelHalfedge::Hole</i>	the corresponding DCEL hole type.

<i>ArrangementDcelHalfedge::X_monotone_curve</i>	the curve type associated with the edge.
--------------------------------------------------	------------------------------------------

Creation

<i>ArrangementDcelHalfedge e;</i>	default constructor.
<i>void e.assign(Self other)</i>	assigns <i>e</i> with the contents of the <i>other</i> halfedge.

Access Functions

<i>Comparison_result e.direction()</i>	returns <i>SMALLER</i> if <i>e</i> 's source vertex is lexicographically smaller than it target, and <i>LARGER</i> if it is lexicographically larger than the target.
<i>bool e.is_on_hole()</i>	determines whether the <i>e</i> lies on an outer CCB of a bounded face, or on an inner CCB (a hole inside a face). The function returns <i>true</i> if <i>e</i> lies on a hole.

All functions below also have *const* counterparts, returning non-mutable pointers or references:

<i>Halfedge* e.opposite()</i>	returns the twin halfedge.
<i>Halfedge* e.prev()</i>	returns the previous halfedge along the chain.
<i>Halfedge* e.next()</i>	returns the next halfedge along the chain.

<i>Vertex*</i>	<i>e.vertex()</i>	returns the target vertex.
<i>Face*</i>	<i>e.face()</i>	returns the incident face. <i>Precondition:</i> <i>e</i> lies on the outer boundary of this face.
<i>Hole*</i>	<i>e.hole()</i>	returns the hole (inner CCB) <i>e</i> belongs to. <i>Precondition:</i> <i>e</i> lies on a hole inside its incident face.
<i>X_monotone_curve&</i>	<i>e.curve()</i>	returns the associated curve.

Modifiers

<i>void</i>	<i>e.set_opposite(Halfedge* opp)</i>	sets the opposite halfedge.
<i>void</i>	<i>e.set_direction(Comparison_result dir)</i>	sets the lexicographical order between <i>e</i> 's source and target vertices to be <i>dir</i> . The direction of the opposite halfedge is also set to the opposite direction. <i>Precondition:</i> <i>dir</i> is either <i>SMALLER</i> or <i>LARGER</i> (and not <i>EQUAL</i>).
<i>void</i>	<i>e.set_prev(Halfedge* prev)</i>	sets the previous halfedge of <i>e</i> along the chain, and updates the cross-pointer <i>prev->next()</i> .
<i>void</i>	<i>e.set_next(Halfedge* next)</i>	sets the next halfedge of <i>e</i> along the chain, and updates the cross-pointer <i>next->prev()</i> .
<i>void</i>	<i>e.set_vertex(Vertex* v)</i>	sets the target vertex.
<i>void</i>	<i>e.set_face(Face* f)</i>	sets the incident face, marking that <i>e</i> lies on the outer CCB of the face <i>f</i> .
<i>void</i>	<i>e.set_hole(Hole* ho)</i>	sets the incident hole, marking that <i>e</i> lies on an inner CCB.
<i>void</i>	<i>e.set_curve(X_monotone_curve* c)</i>	sets the associated curve of <i>e</i> and its opposite halfedge.

ArrangementDcelFace

Definition

A face record in a DCEL data structure. A face may either be unbounded, otherwise it has an incident halfedge along the chain defining its outer boundary. A face may also contain holes and isolated vertices in its interior.

Types

<i>ArrangementDcelFace:: Vertex</i>	the corresponding DCEL vertex type.
<i>ArrangementDcelFace:: Halfedge</i>	the corresponding DCEL halfedge type.
<i>ArrangementDcelFace:: Hole_iterator</i>	a bidirectional iterator over the holes in inside the face. Its value-type is <i>Halfedge*</i> .
<i>ArrangementDcelFace:: Isolated_vertex_iterator</i>	a bidirectional iterator over the isolated vertices in inside the face. Its value-type is <i>Vertex*</i> .

The non-mutable iterators *Hole_const_iterator*, and *Isolated_vertex_const_iterator* are also defined.

Creation

<i>ArrangementDcelFace f;</i>	default constructor.
<i>void f.assign(Self other)</i>	assigns <i>f</i> with the contents of the <i>other</i> face.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

<i>Halfedge*</i>	<i>f.halfedge()</i>	returns an incident halfedge along the outer boundary of the face. If <i>f</i> is the unbounded face, the function returns <i>NULL</i> .
<i>size_t</i>	<i>f.number_of_holes()</i>	returns the number of holes inside <i>f</i> .
<i>Hole_iterator</i>	<i>f.holes_begin()</i>	returns a begin-iterator for the holes inside <i>f</i> .
<i>Hole_iterator</i>	<i>f.holes_end()</i>	returns a past-the-end iterator for the holes inside <i>f</i> .
<i>size_t</i>	<i>f.number_of_isolated_vertices()</i>	returns the number of isolated vertices inside <i>f</i> .
<i>Isolated_vertex_iterator</i>	<i>f.isolated_vertices_begin()</i>	returns a begin-iterator for the isolated vertices inside <i>f</i> .

Isolated_vertex_iterator

f.isolated_vertices_end()

returns a past-the-end iterator for the isolated vertices inside *f*.

Modifiers

void *f.set_halfedge(Halfedge* e)*

sets the incident halfedge.

void *f.add_hole(Halfedge* e)*

adds *e* as a hole inside *f*.

void *f.erase_hole(Hole_iterator it)*

removes the hole that *it* points to from inside *f*.

void *f.add_isolated_vertex(Vertex* v)*

adds *v* as an isolated vertex inside *f*.

void *f.erase_isolated_vertex(Isolated_vertex_iterator it)*

removes the isolated vertex that *it* points to from inside *f*.

ArrangementDcelHole

Definition

A hole record in a DCEL data structure, which stores the face that contains the hole in its interior, along with an iterator for the hole in the holes' container of this face.

Types

ArrangementDcelHole::Face the corresponding DCEL face type.

typedef Face::Hole_iterator

Hole_iterator;

Creation

ArrangementDcelHole ho; default constructor.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

*Face** *ho.face()* returns the incident face, which contains *ho* in its interior.

Hole_iterator *ho.iterator()* returns an iterator for the hole.

Modifiers

void *ho.set_face(Face* f)* sets the incident face.

void *ho.set_iterator(Hole_iterator it)*
sets the hole iterator.

ArrangementDcellIsolatedVertex

Definition

An isolated vertex-information record in a DCEL data structure, which stores the face that contains the isolated vertex in its interior, along with an iterator for the isolated vertex in the isolated vertices' container of this face.

Types

ArrangementDcellIsolatedVertex::Face the corresponding DCEL face type.

```
typedef Face::Isolated_vertex_iterator
        Isolated_vertex_iterator;
```

Creation

ArrangementDcellIsolatedVertex iv; default constructor.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

*Face** *iv.face()* returns the incident face, which contains *iv* in its interior.

Isolated_vertex_iterator
 iv.iterator() returns an iterator for the isolated vertex.

Modifiers

void *iv.set_face(Face* f)* sets the incident face.

void *iv.set_iterator(Isolated_vertex_iterator it)*
 sets the isolated vertex iterator.

CGAL::Arr_dcel_base<V,H,F>

Definition

The *Arr_dcel_base*<*V,H,F*> class is an important ingredient in the definition of DCEL data structures. It serves as a basis class for any instance of the *Dcel* template parameter of the *Arrangement_2* template. In particular it is the basis class of the default *Dcel* template parameter, and the basis class of any extended DCEL. The template parameters *V*, *H*, and *F* must be instantiated with models of the concepts *ArrangementDcelVertex*, *ArrangementDcelHalfedge*, and *ArrangementDcelFace* respectively.

```
#include <CGAL/Arr_dcel_base.h>
```

Is Model for the Concepts

ArrangementDcel

Class Arr_vertex_base<Point>

Definition

The basic DCEL vertex type. Serves as a basis class for an extended vertex record with auxiliary data fields. The *Point* parameter is the type of points associated with the vertices.

Is Model for the Concepts

ArrangementDcelVertex

Class Arr_halfedge_base<Curve>

Definition

The basic DCEL halfedge type. Serves as a basis class for an extended halfedge record with auxiliary data fields. The *Curve* parameter is the type of *x*-monotone curves associated with the vertices.

CGAL::Arr_default_dcel<Traits>

Definition

The default DCEL class used by the *Arrangement_2* class-template is parameterized by a traits class, which is a model of the *ArrangementBasicTraits_2* concept. It simply uses the nested *Traits::Point_2* and *Traits::X_monotone_curve_2* to instantiate the base vertex and halfedge types, respectively. Thus, the default DCEL records store no other information, except for the topological incidence relations and the geometric data attached to vertices and edges.

```
#include <CGAL/Arr_default_dcel.h>
```

Is Model for the Concepts

ArrangementDcel

Inherits From

```
Arr_dcel_base<Arr_vertex_base<typename Traits::Point_2>,
              Arr_halfedge_base<typename Traits::X_monotone_curve_2>,
              Arr_face_base>
```

Types

```
Arr_default_dcel<Traits>:: template <class T> rebind
```

allows the rebinding of the DCEL with a different traits class *T*.

Arr_dcel_base<*V,H,F*> (page [1248](#))

CGAL::Arr_face_extended_dcel<Traits,FData,V,H,F>

Definition

The *Arr_face_extended_dcel<Traits,FData,V,H,F>* class-template extends the DCEL face-records, making it possible to store extra (non-geometric) data with the arrangement faces. The class should be instantiated by an *FData* type which represents the extra data stored with each face.

Note that all types of DCEL features (namely vertex, halfedge and face) are provided as template parameters. However, by default they are defined as follows:

```
V = Arr_vertex_base<typename Traits::Point_2>
H = Arr_halfedge_base<typename Traits::X_monotone_curve_2>
F = Arr_face_base
```

```
#include <CGAL/Arr_extended_dcel.h>
```

CGAL::Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>

Definition

The *Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>* class-template extends the topological-features of the DCEL namely the vertex, halfedge, and face types. While it is possible to maintain extra (non-geometric) data with the curves or points of the arrangement by extending their types respectively, it is also possible to extend the vertex, halfedge, or face types of the DCEL through inheritance. As the technique to extend these types is somewhat cumbersome and difficult for inexperienced users, the *Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>* class-template provides a convenient way to do that. Each one of the three features is extended with a corresponding data type provided as parameters. This class template is also parameterized with a traits class used to extract default values for the vertex, halfedge, and face base classes, which are the remaining three template parameters respectively. The default values follow:

```
V = Arr_vertex_base<typename Traits::Point_2>
H = Arr_halfedge_base<typename Traits::X_monotone_curve_2>
F = Arr_face_base
```

```
#include <CGAL/Arr_extended_dcel.h>
```

Is Model for the Concepts

ArrangementDcel

Inherits From

```
Arr_dcel_base<Arr_extended_vertex<V, VData>,
              Arr_extended_halfedge<H, HData>,
              Arr_extended_face<F, FData> >
```

Types

```
Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>:: template <class T> rebind
```

allows the rebinding of the DCEL with a different traits class *T*.

ArrangementBasicTraits_2

Definition

The basic arrangement-traits concept defines the minimal set of geometric predicates needed for the construction and maintenance of instances of the *Arrangement_2* class, as well as performing simple queries (such as point-location queries) on such arrangements.

A model of this concept must define nested *Point_2* and *X_monotone_curve_2* types, which represent planar points and *x*-monotone curves (a vertical segment is also considered to be *weakly x-monotone*), respectively. The *x*-monotone curves are assumed to be pairwise disjoint in their interiors, so they do not intersect, and their endpoints are representable as *Point_2* objects.

Types

ArrangementBasicTraits_2::Point_2 represents a point on the plane.

ArrangementBasicTraits_2::X_monotone_curve_2
represents a planar (weakly) *x*-monotone curve.

Tags

ArrangementBasicTraits_2::Has_left_category
indicates whether the nested functor *Compare_at_x_left_2* is provided.

Functor Types

ArrangementBasicTraits_2::Compare_x_2
provides the operator :
Comparison_result operator() (Point_2 p1, Point_2 p2)
which returns *SMALLER*, *EQUAL* or *LARGER* according to the *x*-ordering of points *p1* and *p2*.

ArrangementBasicTraits_2::Compare_xy_2
provides the operator :
Comparison_result operator() (Point_2 p1, Point_2 p2)
which returns *SMALLER*, *EQUAL*, or *LARGER* according to the lexicographic *xy*-order of the points *p1* and *p2*.

ArrangementBasicTraits_2:: Construct_min_vertex_2

provides the operator :

Point_2 operator() (X_monotone_curve_2 c)

which returns the lexicographically smaller (left) endpoint of *c*.

ArrangementBasicTraits_2:: Construct_max_vertex_2

provides the operator :

Point_2 operator() (X_monotone_curve_2 c)

which returns the lexicographically larger (right) endpoint of *c*.

ArrangementBasicTraits_2:: Is_vertical_2

provides the operator :

bool operator() (X_monotone_curve_2 c)

which determines whether *c* is a vertical segment.

ArrangementBasicTraits_2:: Compare_y_at_x_2

provides the operator :

Comparison_result operator() (Point_2 p, X_monotone_curve_2 c)

which compares the y-coordinates of *p* and the vertical projection of *p* on *c*, and returns *SMALLER*, *EQUAL* or *LARGER* according to the result.

ArrangementBasicTraits_2:: Compare_y_at_x_left_2

provides the operator :

Comparison_result operator() (X_monotone_curve_2 c1, X_monotone_curve_2 c2, Point_2 p)

which accepts two *x*-monotone curves *c1* and *c2* that have a common right endpoint *p*, and returns *SMALLER*, *EQUAL* or *LARGER* according to the relative position of the two curves immediately to the left of *p*. Note that in case one of the *x*-monotone curves is a vertical segment (emanating downward from *p*), it is always considered to be below the other curve.

ArrangementBasicTraits_2:: Compare_y_at_x_right_2

provides the operator :

Comparison_result operator() (X_monotone_curve_2 c1, X_monotone_curve_2 c2, Point_2 p)

which accepts two *x*-monotone curves *c1* and *c2* that have a common left endpoint *p*, and returns *SMALLER*, *EQUAL* or *LARGER* according to the relative position of the two curves immediately to the right of *p*. Note that in case one of the *x*-monotone curves is a vertical segment emanating upward from *p*, it is always considered to be above the other curve.

ArrangementBasicTraits_2:: Equal_2

provides the operators :

bool operator() (Point_2 p1, Point_2 p2)

which determines whether *p1* and *p2* are geometrically equivalent; and :

bool operator() (X_monotone_curve_2 c1, X_monotone_curve_2 c2)

which determines whether *c1* and *c2* are geometrically equivalent (have the same graph).

ArrangementLandmarkTraits_2

Definition

The landmark-traits concept refines the basic traits concept by adding operations needed for the landmarks point-location strategy, namely — approximating points and connecting points with a simple x -monotone curve.

A model of this concept must define the *Approximate_number_type*, which is used to approximate the coordinates of *Point_2* instances. It is recommended to define the approximated number type as the built-in *double* type.

Refines

ArrangementBasicTraits_2

Types

ArrangementLandmarkTraits_2::Approximate_number_type

the number type used to approximate point coordinates.

Functor Types

ArrangementLandmarkTraits_2::Approximate_2

provides the operator :

Approximate_number_type operator() (Point_2 p, int i)

which returns an approximation of p 's x -coordinate (if $i == 0$), or of p 's y -coordinate (if $i == 1$).

ArrangementLandmarkTraits_2::Construct_x_monotone_curve_2

provides the operator :

X_monotone_curve_2 operator() (Point_2 p1, Point_2 p2)

returns an x -monotone curve connecting $p1$ and $p2$ (i.e., the two input points are its endpoints).

Creation

ArrangementLandmarkTraits_2 traits;

ArrangementBasicTraits_2 (page [1256](#))

ArrangementXMonotoneTraits_2

Definition

This concept refines the basic arrangement-traits concept. A model of this concept is able to handle x -monotone curves that intersect in their interior (and points that coincide with curve interiors). This is necessary for constructing arrangements of sets of intersecting x -monotone curves.

As the resulting structure, represented by the *Arrangement_2* class, stores pairwise interior-disjoint curves, the input curves are split at the intersection points before being inserted into the arrangement. A model of this refined concept therefore needs to compute the intersections (and possibly overlaps) between two x -monotone curves and to support curve splitting. The reverse merge operation is optionally supported.

Refines

ArrangementBasicTraits_2

Tags

ArrangementXMonotoneTraits_2::Has_merge_category indicates whether the nested functors *Are_mergeable_2* and *Merge_2* are provided.

Types

ArrangementXMonotoneTraits_2::Multiplicity the multiplicity type.

Functor Types

ArrangementXMonotoneTraits_2::Intersect_2

provides the operator (templated by the *OutputIterator* type) :

OutputIterator operator() (*X_monotone_curve_2* *c1*, *X_monotone_curve_2* *c2*, *OutputIterator* *oi*)

which computes the intersections of *c1* and *c2* and inserts them in an ascending lexicographic xy -order into the output iterator. The value-type of *OutputIterator* is *CGAL::Object*, where each *Object* either wraps a *pair<Point_2, Multiplicity>* instance, which represents an intersection point with its multiplicity (in case the multiplicity is undefined or not known, it should be set to 0) or an *X_monotone_curve_2* instance, representing an overlapping subcurve of *c1* and *c2*. The operator returns a past-the-end iterator for the output sequence.

ArrangementXMonotoneTraits_2::Split_2

provides the operator :

void operator() (*X_monotone_curve_2* *c*, *Point_2* *p*, *X_monotone_curve_2*& *c1*, *X_monotone_curve_2*& *c2*)

which accepts an input curve *c* and a split point *p* in its interior. It splits *c* at the split point into two subcurves *c1* and *c2*, such that *p* is *c1*'s right endpoint and *c2*'s left endpoint.

The two following functor types are optional. If they are supported, the *Has_merge_category* tag should be defined as *Tag_true* (and *Tag_false* otherwise):

ArrangementXMonotoneTraits_2::Are_mergeable_2

provides the operator :

bool operator() (X_monotone_curve_2 c1, X_monotone_curve_2 c2)

which accepts two *x*-monotone curves *c1* and *c2* that share a common endpoint, and determines whether they can be merged to form a single continuous *x*-monotone curve.

ArrangementXMonotoneTraits_2::Merge_2

provides the operator :

void operator() (X_monotone_curve_2 c1, X_monotone_curve_2 c2, X_monotone_curve_2& c)

which accepts two *mergeable x*-monotone curves *c1* and *c2* (see above), and sets *c* to be the merged curve.

ArrangementTraits_2

Definition

This refined arrangement-traits concept allows the construction of arrangement of *general* planar curves. Models of this concept are used by the free *insert()* functions of the arrangement package and by the *Arrangement_with_history_2* class.

A model of this concept must define the nested *Curve_2* type, which represents a general planar curve that is not necessarily *x*-monotone and is not necessarily connected. Such curves are eventually subdivided into *x*-monotone subcurves and isolated points (represented by the *Point_2* and *X_monotone_curve_2* types, defined in the basic traits concept).

Refines

ArrangementXMonotoneTraits_2

Types

ArrangementTraits_2::Curve_2 represents a general planar curve.

Functor Types

ArrangementTraits_2::Make_x_monotone_2

provides the operator (parameterized by the *OutputIterator* type) :
OutputIterator operator() (Curve_2 c, OutputIterator oi)
 which subdivides the input curve *c* into *x*-monotone subcurves and isolated points, and inserts the results into a container through the given output iterator. The value type of *OutputIterator* is *CGAL::Object*, where each *Object* wraps either an *X_monotone_curve_2* instance or a *Point_2* instance. The operator returns a past-the-end iterator for the output sequence.

CGAL::Arr_segment_traits_2<Kernel>

Definition

The traits class *Arr_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allow the construction and maintenance of arrangements of line segments. It should be parameterized with a CGAL-kernel model that is templated in turn with a number type. To avoid numerical errors and robustness problems, the number type should support exact rational arithmetic — that is, the number type should support the arithmetic operations $+$, $-$, \times and \div that should be carried out without loss of precision.

For example, instantiating the traits template with kernels such as *Cartesian<Quotient<MP_Float> >*, or *Homogeneous<Gmpz>* ensures the exact and robust operation of the application. In particular, the *Cartesian<Gmpq>* achieves the fastest running times in most cases. Using other (inexact) number types (for example, instantiating the template with *Simple_cartesian<double>*) is possible at the user's own risk: selecting an inexact number type usually leads to faster running time at the expense of possible robustness problems.

For optimal performance, we recommend instantiating the traits class with the default *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Arr_segment_traits_2<Kernel> defines *Kernel::Point_2* as its point type. However, it does *not* define *Kernel::Segment_2* as its curve type, as one may expect. The reason is that the kernel segment is represented by its two endpoints only, while the traits class needs to store extra data with its segments, in order to efficiently operate on them. Nevertheless, the nested *X_monotone_curve_2* and *Curve_2* types (in this case both types refer to the same class, as every line segment is (weakly) *x*-monotone) are however convertible to the *Kernel::Segment_2*.

Arr_segment_traits_2<Kernel> achieves faster running times than the *Arr_non_caching_segment_traits_2<Kernel>* traits-class, when arrangements with relatively many intersection points are constructed. It also allows for working with less accurate, yet computationally efficient number types, such as *Quotient<MP_Float>*, which represents floating-point numbers with an unbounded mantissa, but with a bounded exponent. Using this traits class is therefore highly recommended for almost all applications that rely on arrangements of line segments. On the other hand, *Arr_segment_traits_2<Kernel>* uses more space and stores extra data with each segment, so constructing arrangements of huge sets of non-intersecting segments (or segments that intersect very sparsely) could be more efficient with the *Arr_non_caching_segment_traits_2* traits-class.

```
#include <CGAL/Arr_segment_traits_2.h>
```

ArrangementLandmarkTraits_2

CGAL::Arr_non_caching_segment_basic_traits_2<Kernel>

Definition

The traits class *Arr_non_caching_segment_basic_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allow the construction and maintenance of arrangements of sets of pairwise interior-disjoint line segments. It is templated with a CGAL-*Kernel* model, and it is derived from it. This traits class is a thin layer above the parameterized kernel. It inherits the *Point_2* from the kernel and its *X_monotone_curve_2* type is defined as *Kernel::Segment_2*. Most traits-class functor are inherited from the kernel functor, and the traits class only supplies the necessary functors that are not provided by the kernel. The kernel is parameterized with a number type, which should support the arithmetic operations $+$, $-$ and \times in an exact manner in order to avoid robustness problems. Using *Cartesian<MP_Float>* or *Cartesian<Gmpz>* are possible instantiations for the kernel. Using other (inexact) number types (for example, instatiating the template with *Simple_cartesian<double>*) is also possible, at the user's own risk.

```
#include <CGAL/Arr_non_caching_segment_basic_traits_2.h>
```

ArrangementLandmarkTraits_2

CGAL::Arr_non_caching_segment_traits_2<Kernel>

Definition

The traits class *Arr_non_caching_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allows the construction and maintenance of arrangements of line segments. It is parameterized with a CGAL-*Kernel* type, and it is derived from it. This traits class is a thin layer above the parameterized kernel. It inherits the *Point_2* from the kernel and its *X_monotone_curve_2* and *Curve_2* types are both defined as *Kernel::Segment_2*. Most traits-class functor are inherited from the kernel functor, and the traits class only supplies the necessary functors that are not provided by the kernel. The kernel is parameterized with a number type, which should support exact rational arithmetic in order to avoid robustness problems, although other number types could be used at the user's own risk.

The traits-class implementation is very simple, yet may lead to a cascaded representation of intersection points with exponentially long bit-lengths, especially if the kernel is parameterized with a number type that does not perform normalization (e.g. *Quotient<MP_Float>*). The *Arr_segment_traits_2* traits class avoids this cascading problem, and should be the default choice for implementing arrangements of line segments. It is recommended to use *Arr_non_caching_segment_traits_2<Kernel>* only for very sparse arrangements of huge sets of input segments.

```
#include <CGAL/Arr_non_caching_segment_traits_2.h>

Arr_segment_traits_2<Kernel>

CGAL::Arr_polyline_traits_2<SegmentTraits>

Definition

The traits class *Arr_polyline_traits_2<SegmentTraits>* is a model of the *ArrangementTraits_2* concept. It handles piecewise linear curves, commonly referred to as polylines. Each polyline is a chain of segments, where each two neighboring segments in the chain share a common endpoint. The traits class exploits the functionality of the *SegmentTraits* template-parameter to handle the segments that comprise the polyline curves.

The class instantiated for the template parameter *SegmentTraits* must be a model of the *ArrangementTraits_2* concept that handles line segments (e.g., *Arr_segment_traits_2<Kernel>* or *Arr_non_caching_segment_cached_traits_2<Kernel>*, where the first alternative is recommended).

The number type used by the injected segment traits should support exact rational arithmetic (that is, the number type should support the arithmetic operations $+$, $-$, \times and \div that should be carried out without loss of precision), in order to avoid robustness problems, although other inexact number types could be used at the user's own risk.

```
#include <CGAL/Arr_polyline_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

ArrangementLandmarkTraits_2

Class Arr_polyline_traits_2<SegmentTraits>::Curve_2

The *Curve_2* class nested within the polyline traits is used to represent general continuous piecewise-linear curves (a polyline can be self-intersecting) and support their construction from any range of points.

The copy and default constructor as well as the assignment operator are provided for polyline curves. In addition, an *operator<<* for the curves is defined for standard output streams, and an *operator>>* for the curves is defined for standard input streams.

Types

Arr_polyline_traits_2<SegmentTraits>::Curve_2::const_iterator

A bidirectional iterator that allows traversing the points that comprise a polyline curve.

Arr_polyline_traits_2<SegmentTraits>::Curve_2::const_reverse_iterator

A bidirectional iterator that allows traversing the points that comprise a polyline curve.

Creation

Arr_polyline_traits_2<SegmentTraits>::Curve_2 pi;

default constructor that constructs an empty polyline.

template <class InputIterator>

Arr_polyline_traits_2<SegmentTraits>::Curve_2 pi(Iterator first, Iterator last);

constructs a polyline defined by the given range of points *[first, last)* (the value-type of *InputIterator* must be *SegmentTraits::Point_2*. If the range contains $(n + 1)$ points labeled (p_0, p_1, \dots, p_n) , the generated polyline consists of n segments, where the k th segment is defined by the endpoints $[p_{k-1}, p_k]$. The first point in the range is considered as the source point of the polyline while the last point is considered as its target.

Precondition: There are at least two points in the range.

Access Functions

<i>size_t</i>	<i>pi.points()</i>	returns the number of points that comprise the polyline. Note that if there are n points in the polyline, it is comprised of $(n - 1)$ segments.
---------------	--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------

<i>const_iterator</i>	<i>pi.begin()</i>	returns an iterator pointing at the source point of the polyline.
-----------------------	-------------------	-------------------------------------------------------------------

<i>const_iterator</i>	<i>pi.end()</i>	returns an iterator pointing after the end of the polyline.
-----------------------	-----------------	-------------------------------------------------------------

<i>const_iterator</i>	<i>pi.rbegin()</i>	returns an iterator pointing at the target point of the polyline.
-----------------------	--------------------	-------------------------------------------------------------------

<i>const_iterator</i>	<i>pi.rend()</i>	returns an iterator pointing before the beginning of the polyline.
-----------------------	------------------	--------------------------------------------------------------------

<i>size_t</i>	<i>pi.size()</i>	returns the number of line segments comprising the polyline (equivalent to <i>pi.points() - 1</i>).
---------------	------------------	------------------------------------------------------------------------------------------------------

typename SegmentTraits::X_monotone_curve_2

<i>pi[size_t k]</i>	returns the k th segment of the polyline. <i>Precondition:</i> k is not greater or equal to <i>pi.size() - 1</i> .
----------------------	---------------------------------------------------------------------------------------------------------------------------

<i>Bbox_2</i>	<i>pi.bbox()</i>	return a bounding box of the polyline <i>pi</i> .
---------------	------------------	---------------------------------------------------

Operations

<i>void</i>	<i>pi.push_back(Point_2 p)</i>	adds a new point to the polyline, which becomes the new target point of <i>pi</i> .
-------------	---------------------------------	-------------------------------------------------------------------------------------

void *pi.clear()* resets the polyline.

Class `Arr_polyline_traits_2<SegmentTraits>::X_monotone_curve_2`

The *X_monotone_curve_2* class nested within the polyline traits is used to represent *x*-monotone piecewise linear curves. It inherits from the *Curve_2* type. It has a default constructor and a constructor from a range of points, just like the *Curve_2* class. However, there is precondition that the point range define an *x*-monotone polyline.

The points that define the *x*-monotone polyline are always stored in an ascending lexicographical *xy*-order, so their order may be reversed with respect to the input sequence. Also note that the *x*-monotonicity ensures that an *x*-monotone polyline is never self-intersecting (thus, a self-intersecting polyline will be subdivided to several interior-disjoint *x*-monotone subcurves).

Arr_segment_traits_2<Kernel>

Arr_non_caching_segment_traits_2<Kernel>

CGAL::Arr_circle_segment_traits_2<Kernel>

Definition

The class *Arr_circle_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept and can be used to construct and maintain arrangements of circular arcs and line segments.

The traits class must be instantiated with a geometric kernel, such that the supporting circles of the circular arcs are of type *Kernel::Circle_2* and the supporting lines of the line segments are of type *Kernel::Line_2*. Thus, the coordinates of the center of supporting circles, and its squared radius are of type *Kernel::FT*, which should be an exact rational number-type; similarly, the coefficients of each supporting line $ax + by + c = 0$ are also of type *Kernel::FT*. Note however that the intersection point between two such arcs do not have rational coordinates in general. For this reason, we do not require the endpoints of the input arcs and segments to have rational coordinates.

The nested *Point_2* type defined by the traits class is therefore *different* than the *Kernel::Point_2* type. Its coordinates are of type *CoordNT*, and represent real numbers obtained from solving quadratic equations with rational coordinates. A number of type *CoordNT* can therefore be expressed as $\alpha + \beta\sqrt{\gamma}$, where α , β and γ are all rational numbers. The definition of the curve and *x*-monotone curve types nested in the traits class are detailed below.

```
#include <CGAL/Arr_circle_segment_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Class Arr_circle_segment_traits_2<Kernel>::CoordNT

The *CoordNT* number-type nested within the traits class represents an algebraic number of degree 2; it can be represented as $\alpha + \beta\sqrt{\gamma}$, where α , β and γ are all rational numbers of type *Kernel::FT*.

Types

Arr_circle_segment_traits_2<Kernel>::CoordNT::Rational
the *Kernel::FT* type.

Creation

```
Arr_circle_segment_traits_2<Kernel>::CoordNT x;  
creates a variable whose value is 0.
```

```
Arr_circle_segment_traits_2<Kernel>::CoordNT x(Rational alpha);  
creates a variable whose value is the rational number  $\alpha$ .
```

Arr_circle_segment_traits_2<Kernel>::CoordNT *x*(*Rational* *alpha*, *Rational* *beta*, *Rational* *gamma*);

creates a variable whose value is the algebraic number $\alpha + \beta\sqrt{\gamma}$.

Access Functions

<i>bool</i>	<i>x.is_rational()</i>	determines whether <i>x</i> is rational.
<i>Rational</i>	<i>x.alpha()</i>	returns α .
<i>Rational</i>	<i>x.beta()</i>	returns β (0 if <i>x</i> is rational).
<i>Rational</i>	<i>x.gamma()</i>	returns γ (0 if <i>x</i> is rational).

Operators

The *CoordNT* number-type supports all arithmetic operations with rational numbers of type *Kernel::FT*. For example, it is possible to compute $x + q$, $q - x$, $x += q$, etc. where *q* is rational.

The global functions *CGAL::sign(x)*, *CGAL::square(x)*, *CGAL::to_double(x)* and *CGAL::compare(x,y)*, where *x* and *y* are of type *CoordNT*, are also supported.

Class *Arr_circle_segment_traits_2<Kernel>::Point_2*

The *Point_2* number-type nested within the traits class represents a Cartesian point whose coordinates are algebraic numbers of type *CoordNT*.

Types

Arr_circle_segment_traits_2<Kernel>::Point_2:: Rational

the *Kernel::FT* type.

Arr_circle_segment_traits_2<Kernel>::Point_2:: CoordNT

the algebraic number-type.

Creation

Arr_circle_segment_traits_2<Kernel>::Point_2 *p*;

default constructor.

Arr_circle_segment_traits_2<Kernel>::Point_2 *p*(*Rational* *x*, *Rational* *y*);

creates the point (*x*,*y*).

Arr_circle_segment_traits_2<Kernel>::Point_2 *p*(*CoordNT* *x*, *CoordNT* *y*);

creates the point (*x*,*y*).

Access Functions

CoordNT *p.x()* returns the *x*-coordinate.

CoordNT *p.y()* returns the *y*-coordinate.

Class *Arr_circle_segment_traits_2<Kernel>::Curve_2*

The *Curve_2* class nested within the traits class can represent arbitrary circular arcs, full circles and line segments and support their construction in various ways. The copy and default constructor as well as the assignment operator are provided. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Segment_2* *seg*);

constructs an curve corresponding to the line segment *seg*.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *source*,
typename Kernel::Point_2 *target*)

constructs an curve corresponding to the line segment directed from *source* to *target*, both having rational coordinates.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Line_2* *line*,
Point_2 *source*,
Point_2 *target*)

constructs an curve corresponding to the line segment supported by the given line, directed from *source* to *target*. Note that the two endpoints may have one-root coordinates.

Precondition: Both endpoints must lie on the given supporting line.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Circle_2* *circ*);

constructs an curve corresponding to the given circle. *circ* has a center point with rational coordinates and its *squared* radius is rational.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *c*,
typename Kernel::FT *r*,
Orientation *orient* = *COUNTERCLOCKWISE*)

constructs an curve corresponding to a circle centered at the rational point *c* whose radius *r* is rational.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Circle_2* *circ*,
Point_2 *source*,
Point_2 *target*)

constructs a circular arc supported by *circ*, which has a center point with rational coordinates and whose *squared* radius is rational, with the given endpoints. The orientation of the arc is the same as the orientation of *circ*.

Precondition: Both endpoints must lie on the given supporting circle.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *c*,
typename Kernel::FT *r*,
Orientation *orient*,
Point_2 *source*,
Point_2 *target*)

constructs a circular arc supported by a circle centered at the rational point *c* whose radius *r* is rational, directed from *source* to *target* with the given orientation.

Precondition: Both endpoints must lie on the supporting circle.

Arr_circle_segment_traits_2<Kernel>::Curve_2 *cv*(*typename Kernel::Point_2* *source*,
typename Kernel::Point_2 *mid*,
typename Kernel::Point_2 *target*)

constructs an circular arc whose endpoints are *source* and *target* that passes through *mid*. All three points have rational coordinates.

Precondition: The three points must not be collinear.

Access Functions

<i>bool</i>	<i>cv.is_full()</i>	indicates whether the curve represents a full circle.
<i>Point_2</i>	<i>cv.source()</i>	returns the source point.
<i>Point_2</i>	<i>cv.target()</i>	<i>Precondition:</i> <i>cv</i> is not a full circle. returns the target point.
		<i>Precondition:</i> <i>cv</i> is not a full circle.
<i>Orientation</i>	<i>cv.orientation()</i>	returns the orientation of the curve (<i>COLLINEAR</i> in case of line segments).
<i>bool</i>	<i>cv.is_linear()</i>	determines whether <i>cv</i> is a line segment.
<i>bool</i>	<i>cv.is_circular()</i>	determines whether <i>cv</i> is a circular arc.

typename Kernel::Line_2

cv.supporting_line() returns the supporting line of *cv*.
Precondition: *cv* is a line segment.

typename Kernel::Circle_2

cv.supporting_circle()

returns the supporting circle of *cv*.

Precondition: *cv* is a circular arc.

Class Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the traits class can represent *x*-monotone and line segments (which are always weakly *x*-monotone). The copy and default constructor as well as the assignment operator are provided. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2 xcv(typename Kernel::Point_2 source,
typename Kernel::Point_2 target)

constructs an curve corresponding to the line segment directed from *source* to *target*, both having rational coordinates.

Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2 xcv(typename Kernel::Line_2 line,
Point_2 source,
Point_2 target)

constructs an curve corresponding to the line segment supported by the given line, directed from *source* to *target*. Note that the two endpoints may have one-root coordinates.

Precondition: Both endpoints must lie on the given supporting line.

Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2 xcv(typename Kernel::Circle_2 circ,
Point_2 source,
Point_2 target,
Orientation orient)

constructs a circular arc supported by *circ*, which has a center point with rational coordinates and whose *squared* radius is rational, with the given endpoints. The orientation of the arc is determined by *orient*.

Precondition: Both endpoints must lie on the given supporting circle.

Precondition: The circular arc is *x*-monotone.

Access Functions

Point_2 *xcv.source()* returns the source point of *xcv*.

<i>Point_2</i>	<i>xcv.target()</i>	returns the target point of <i>xcv</i> .
<i>Point_2</i>	<i>xcv.left()</i>	returns the left (lexicographically smaller) endpoint of <i>xcv</i> .
<i>Point_2</i>	<i>xcv.right()</i>	returns the right (lexicographically larger) endpoint of <i>xcv</i> .
<i>Orientation</i>	<i>xcv.orientation()</i>	returns the orientation of the curve (<i>COLLINEAR</i> in case of line segments).
<i>bool</i>	<i>xcv.is_linear()</i>	determines whether <i>xcv</i> is a line segment.
<i>bool</i>	<i>xcv.is_circular()</i>	determines whether <i>xcv</i> is a circular arc.
<i>typename Kernel::Line_2</i>		
	<i>xcv.supporting_line()</i>	returns the supporting line of <i>xcv</i> . <i>Precondition: xcv is a line segment.</i>
<i>typename Kernel::Circle_2</i>		
	<i>xcv.supporting_circle()</i>	returns the supporting circle of <i>xcv</i> . <i>Precondition: xcv is a circular arc.</i>
<i>Bbox_2</i>	<i>xcv.bbox()</i>	returns a bounding box of the arc <i>xcv</i> .

CGAL::Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>

Definition

The class `Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>` is a model of the *ArrangementTraits_2* concept and can be used to construct and maintain arrangements of bounded segments of algebraic curves of degree 2 at most, also known as *conic curves*.

A general conic curve C is the locus of all points (x,y) satisfying the equation: $rx^2 + sy^2 + txy + ux + vy + w = 0$, where:

- If $4rs - t^2 > 0$, C is an ellipse. A special case occurs when $r = s$ and $t = 0$, when C becomes a circle.
- If $4rs - t^2 < 0$, C is a hyperbola.
- If $4rs - t^2 = 0$, C is a parabola. A degenerate case occurs when $r = s = t = 0$, when C is a line.

A *bounded conic arc* is defined as either of the following:

- A full ellipse (or a circle) C .
- The tuple $\langle C, p_s, p_t, o \rangle$, where C is the supporting conic curve, with the arc endpoints being p_s and p_t (the source and target points, respectively). The orientation o indicates whether we proceed from p_s to p_t in a clockwise or in a counterclockwise direction. Note that C may also correspond to a line or to pair of lines — in this case o may specify a *COLLINEAR* orientation.

A very useful subset of the set of conic arcs are line segments and circular arcs, as arrangements of circular arcs and line segments have some interesting applications (e.g. offsetting polygons, motion planning for a disc robot, etc.). Circular arcs and line segment are simpler objects and can be dealt with more efficiently than arbitrary arcs. For these reasons, it is possible to construct conic arcs from segments and from circles. Using these constructors is highly recommended: It is more straightforward and also speeds up the arrangement construction. However, in case the set of input curves contain only circular arcs and line segments, it is recommended to use the `Arr_circle_segment_2` class to achieve faster running times.

In our representation, all conic coefficients (namely r, s, t, u, v, w) must be rational numbers. This guarantees that the coordinates of all arrangement vertices (in particular, those representing intersection points) are algebraic numbers of degree 4 (a real number α is an algebraic number of degree d if there exist a polynomial p with integer coefficient of degree d such that $p(\alpha) = 0$). We therefore require separate representations of the curve coefficients and the point coordinates. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, it can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The other template parameters, *RatKernel* and *AlgKernel* should be geometric kernels templated with the *NtTraits::Rational* and *NtTraits::Algebraic* number types, respectively. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Rational>* and *Cartesian<NtTraits::Algebraic>* instantiating the two kernel types, respectively. The number types in this case are provided by the CORE library, with its ability to exactly represent simple algebraic numbers.

The traits class inherits its point type from *AlgKernel::Point_2*, and defines a curve and x -monotone curve types, as detailed below.

```
#include <CGAL/Arr_conic_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

ArrangementLandmarkTraits_2

Class **Arr_conic_traits_2**<RatKernel,AlgKernel,NtTraits>::Curve_2

The *Curve_2* class nested within the conic-arc traits can represent arbitrary conic arcs and support their construction in various ways. The copy and default constructor as well as the assignment and equality operators are provided for conic arcs. In addition, an *operator<<* for the curves is defined for standard output streams.

Types

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2:: *Rational*

the *NtTraits::Rational* type (and also the *RatKernel::FT* type).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2:: *Algebraic*

the *NtTraits::Algebraic* type (and also the *AlgKernel::FT* type).

Creation

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(typename *RatKernel::Segment_2* *seg*);

constructs an arc corresponding to the line segment *seg*.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(typename *RatKernel::Circle_2* *circ*);

constructs an arc corresponding to the full circle *circ* (note that this circle has a center point with rational coordinates and rational squared radius).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(typename *RatKernel::Circle_2* *circ*,
Orientation *o*,
Point_2 *ps*,
Point_2 *pt*)

constructs a circular arc supported by the circle *circ*, going in the given orientation *o* from the source point *ps* to its target point *pt*.

Precondition: *ps* and *pt* both lie on the circle *circ*.

Precondition: *o* is not *COLLINEAR*.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*typename RatKernel::Point_2* *p1*,
typename RatKernel::Point_2 *p2*,
typename RatKernel::Point_2 *p3*)

constructs a circular arc going from *p1* (its source point) through *p2* to *p3* (its target point). Note that all three points have rational coordinates. The orientation of the arc is determined automatically.

Precondition: The three points are not collinear.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*Rational* *r*,
Rational *s*,
Rational *t*,
Rational *u*,
Rational *v*,
Rational *w*)

constructs a conic arc that corresponds to the full conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$.

Precondition: As a conic arc must be bounded, the given curve must be an ellipse, that is $4rs - t^2 > 0$.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*Rational* *r*,
Rational *s*,
Rational *t*,
Rational *u*,
Rational *v*,
Rational *w*,
Orientation *o*,
Point_2 *ps*,
Point_2 *pt*)

constructs a conic arc supported by the conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$, going in the given orientation *o* from the source point *ps* to its target point *pt*.

Precondition: *ps* and *pt* both satisfy the equation of the supporting conic curve and define a bounded segment of this curve (e.g. in case of a hyperbolic arc, both point should be located on the same branch of the hyperbola).

Precondition: *o* is not *COLLINEAR* if the supporting conic is curves, and must be *COLLINEAR* if it is not curved (a line or a line-pair).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 *a*(*typename RatKernel::Point_2* *p1*,
typename RatKernel::Point_2 *p2*,
typename RatKernel::Point_2 *p3*,
typename RatKernel::Point_2 *p4*,

typename RatKernel::Point_2 p5)

constructs a conic arc going from $p1$ (its source point) through $p2$, $p3$ and $p4$ (in this order) to $p5$ (its target point). Note that all five points have rational coordinates. The orientation of the arc is determined automatically.

Precondition: No three points of the five are not collinear.

Precondition: The five points define a valid arc, in their given order.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(Rational r,
Rational s,
Rational t,

Rational v2,
Rational w2)

constructs a conic arc supported by the conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$, going in the given orientation o from its source point to its target point. In this case only some approximations of the endpoints (*app_ps* and *app_pt*, respectively) is available, and their exact locations are given implicitly, specified by the intersections of the supporting conic curve with $r_1x^2 + s_1y^2 + t_1xy + u_1x + v_1y + w_1 = 0$ and $r_2x^2 + s_2y^2 + t_2xy + u_2x + v_2y + w_2 = 0$, respectively.

Precondition: The two auxiliary curves specifying the endpoints really intersect with the supporting conic curve, such that the arc endpoints define a bounded segment of the supporting curve (e.g. in case of a hyperbolic arc, both point should be located on the same branch of the hyperbola).

Precondition: o is not *COLLINEAR* if the supporting conic is curves, and must be *COLLINEAR* if it is not curved (a line or a line-pair).

Access Functions

<i>bool</i>	<i>a.is_valid()</i>	indicates whether <i>a</i> is a valid conic arc. As the precondition to some of the constructor listed above are quite complicated, their violation does not cause the program to abort. Instead, the constructed arc is invalid (a defaultly constructed arc is also invalid). It is however recommended to check that a constructed arc is valid before inserting it to an arrangement, as this operation <i>will</i> cause the program to abort.
<i>bool</i>	<i>a.is_x_monotone()</i>	determines whether the arc is <i>x</i> -monotone, namely each vertical line intersects it at most once. A vertical line segment is also considered (weakly) <i>x</i> -monotone.
<i>bool</i>	<i>a.is_y_monotone()</i>	determines whether the arc is <i>y</i> -monotone, namely each horizontal line intersects it at most once. A horizontal line segment is also considered (weakly) <i>x</i> -monotone.
<i>bool</i>	<i>a.is_full_conic()</i>	indicates whether the arc represents a full conic curve (en ellipse or a circle).

The six following methods return the coefficients of the supported conic, after their conversion to integer number (represented by the *Integer* type of the *NtTraits* class):

<i>typename NtTraits::Integer</i>	<i>a.r()</i>	returns the coefficient of x^2 .
<i>typename NtTraits::Integer</i>	<i>a.s()</i>	returns the coefficient of t^2 .
<i>typename NtTraits::Integer</i>	<i>a.t()</i>	returns the coefficient of xy .
<i>typename NtTraits::Integer</i>	<i>a.u()</i>	returns the coefficient of x .
<i>typename NtTraits::Integer</i>	<i>a.v()</i>	returns the coefficient of y .
<i>typename NtTraits::Integer</i>	<i>a.w()</i>	returns the free coefficient.
<i>Point_2</i>	<i>a.source()</i>	returns the source point of the arc. <i>Precondition:</i> <i>a</i> is not a full conic curve.
<i>Point_2</i>	<i>a.target()</i>	returns the target point of the arc. <i>Precondition:</i> <i>a</i> is not a full conic curve.
<i>Orientation</i>	<i>a.orientation()</i>	returns the orientation of the arc.
<i>Bbox_2</i>	<i>a.bbox()</i>	return a bounding box of the arc <i>a</i> .

Operations

<i>void</i>	<i>a.set_source(Point_2 ps)</i>	sets a new source point for the conic arc. <i>Precondition:</i> <i>ps</i> lies on the supporting conic of <i>a</i> .
<i>void</i>	<i>a.set_target(Point_2 pt)</i>	sets a new target point for the conic arc. <i>Precondition:</i> <i>pt</i> lies on the supporting conic of <i>a</i> .

Class **Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::X_monotone_curve_2**

The *X_monotone_curve_2* class nested within the conic-arc traits is used to represent *x*-monotone conic arcs. It inherits from the *Curve_2* type, therefore supports the access methods and the operations listed above.

For efficiency reasons, we recommend users not to construct x -monotone conic arc directly, but rather use the *Make_x_monotone_2* functor supplied by the conic-arc traits class to convert conic curves to x -monotone curves.

Creation

Arr_conic_traits_2<*RatKernel*,*AlgKernel*,*NtTraits*>::*X_monotone_curve_2* *xa*(*Curve_2* *arc*);

converts the given arc to an x -monotone arc.

Precondition: *arc* is x -monotone.

Access Functions

<i>Point_2</i>	<i>xa.left()</i>	returns the left (lexicographically smaller) endpoint of <i>xa</i> .
<i>Point_2</i>	<i>xa.right()</i>	returns the right (lexicographically larger) endpoint of <i>xa</i> .

CGAL::Arr_rational_arc_traits_2<AlgKernel,NtTraits>

Definition

The traits class *Arr_rational_arc_traits_2<AlgKernel,NtTraits>* is a model of the *ArrangementTraits_2* concept. It handles bounded segments of rational functions, referred to as *rational arcs*, and enables the construction and maintenance of arrangements of such arcs. A rational function $y = \frac{P(x)}{Q(x)}$ is defined by two polynomials P and Q of arbitrary degrees. In particular, if $Q(x) = 1$ then the function is a simple polynomial function. A bounded rational arc is defined by the graph of a rational function over some interval $[x_{\min}, x_{\max}]$, where Q does not have any real roots in this interval (thus the arc does not contain any poles). Rational functions, and polynomial functions in particular, are not only interesting in their own right, they are also very useful for approximating or interpolating more complicated curves.

In our representation, all polynomial coefficients (the coefficients of P and Q) must be rational numbers. This guarantees that the x -coordinates of all arrangement vertices (in particular, those representing intersection points) can be represented as roots of polynomials with integer coefficients — namely, algebraic numbers. The y -coordinates can be obtained by simple arithmetic operations on the x -coordinates, hence they are also algebraic numbers.

We therefore require separate representations of the curve coefficients and the point coordinates. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, it can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The *AlgKernel* template-parameter should be a geometric kernel templated with the *NtTraits::Algebraic* number-type. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Algebraic>* instantiating the kernel. The number types in this case are provided by the *CORE* library, with its ability to exactly represent simple algebraic numbers.

The traits class defined its point type to be *AlgKernel::Point_2*, and defines a curve type (and an identical x -monotone curve type, as a rational arc is always x -monotone by definition) as detailed below.

```
#include <CGAL/Arr_rational_arc_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Class Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2

The *Curve_2* class nested within the rational-arc traits is used to represent rational arcs and support their construction from a single polynomial and the range where the arc is defined or a pair of polynomials and a pair of corresponding ranges. The copy and default constructor as well as the assignment operator are provided for polyline curves. In addition, an *operator<<* for the curves is defined for standard output streams.

Types

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2::Rat_vector

A vector of rational numbers (equivalent to *std::vector<typename NtTraits::Rational>*).

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2:: Polynomial

the *NtTraits::Polynomial* type (a polynomial with integer coefficients).

Creation

Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a;

default constructor.

*Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a(Rat_vector p_coeffs,
typename NtTraits::Algebraic s_x,
typename NtTraits::Algebraic t_x)*

constructs an arc supported by the polynomial $y = P(x)$, defined over the interval $[x_s, x_t]$, given by the x -coordinates of the arc's source and target. The vector *p_coeffs* specifies the coefficients of $P(x)$, where the polynomial degree is *p_coeffs.size() - 1* and $p[k]$ is the coefficient of x^k in P .
Precondition: $s_x \neq t_x$.

*Arr_rational_arc_traits_2<AlgKernel,NtTraits>::Curve_2 a(Rat_vector p_coeffs,
Rat_vector q_coeffs,
typename NtTraits::Algebraic s_x,
typename NtTraits::Algebraic t_x)*

constructs an arc supported by the rational function $y = \frac{P(x)}{Q(x)}$, defined over the interval $[s_x, t_x]$, given by the x -coordinates of the arc's source and target. The vectors *p_coeffs* and *q_coeffs* specify the coefficients of $P(x)$ and $Q(x)$, respectively (see above).
Precondition: $x_{min} < x_{max}$.
Precondition: For each $x_{min} \leq x \leq x_{max}$, $Q(x) \neq 0$.

Access Functions

bool a.is_valid()

indicates whether *a* is a valid rational arc. As the precondition $Q(x) \neq 0$ to the constructor from two polynomials is quite complicated, its violation does not cause the program to abort. Instead, the constructed arc is invalid (a defaultly constructed arc is also invalid). It is however recommended to check that a constructed arc is valid before inserting it to an arrangement, as this operation *will* cause the program to abort.

Polynomial a.numerator()

returns a polynomial with integer coefficients equivalent to $P(x)$.

<i>Polynomial</i>	<i>a.denominator()</i>	returns a polynomial with integer coefficients equivalent to $Q(x)$.
<i>Point_2</i>	<i>a.source()</i>	returns the source point of the arc. <i>Precondition:</i> a is not a full conic curve.
<i>Point_2</i>	<i>a.target()</i>	returns the target point of the arc. <i>Precondition:</i> a is not a full conic curve.
<i>Point_2</i>	<i>a.left()</i>	returns the left (lexicographically smaller) endpoint of a .
<i>Point_2</i>	<i>a.right()</i>	returns the right (lexicographically larger) endpoint of a .

CGAL::Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>

Definition

The class *Arr_curve_data_traits_2*<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*> is a model of the *ArrangementTraits_2* concept and serves as a decorator class that allows the extension of the curves defined by the base traits-class (the *Tr* parameter), which serves as a geometric traits-class (a model of the *ArrangementTraits_2* concept), with extraneous (non-geometric) data fields.

The traits class inherits its point type from *Traits::Point_2*, and defines an extended *Curve_2* and *X_monotone_curve_2* types, as detailed below.

Each *Curve_2* object is associated with a single data field of type *CData*, and each *X_monotone_curve_2* object is associated with a single data field of type *XData*. When a curve is subdivided into *x*-monotone subcurves, its data field is converted using the conversion functor, which is specified by the *Cnv* template-parameter, and the resulting objects is copied to all *X_monotone_curve_2* objects induced by this curve. The conversion functor should provide an operator with the following prototype:

```
XData operator() (const CData& d) const;
```

By default, the two data types are the same, so the conversion operator is trivial:

```
CData = XData
```

```
Cnv = _Default_convert_functor<CData,XData>
```

In case two (or more) *x*-monotone curves overlap, their data fields are merged to a single field, using the merge functor, which is specified by the *Mrg* template-parameter. This functor should provide an operator with the following prototype:

```
XData operator() (const XData& d1, const XData& d2) const;
```

which returns a single data object that represents the merged data field of *d1* and *d2*. The *x*-monotone curve that represents the overlap is associated with the output of this functor.

```
#include <CGAL/Arr_curve_data_traits_2.h>
```

Is Model for the Concepts

```
ArrangementTraits_2
```

Types

```
typedef Tr Base_traits_2; the base traits-class.
```

```
typedef typename Base_traits_2::Curve_2
```

```
Base_curve_2; the base curve.
```

```
typedef typename Base_traits_2::X_monotone_curve_2
```

```
Base_x_monotone_curve_2;
```

```
the base x-monotone curve curve.
```

<i>typedef Mrg</i>	<i>Merge;</i>	the merge functor.
<i>typedef Cnv</i>	<i>Convert;</i>	the conversion functor.
<i>typedef CData</i>	<i>Curve_data;</i>	the type of data associated with curves.
<i>typedef XData</i>	<i>X_monotone_curve_data;</i>	the type of data associated with <i>x</i> -monotone curves.

Inherits From

Base_traits_2

Class **Arr_curve_data_traits_2**<Tr,XData,Mrg,CData,Cnv>::Curve_2

The *Curve_2* class nested within the curve-data traits extends the *Base_traits_2::Curve_2* type with an extra data field of type *Data*.

Inherits From

Base_curve_2

Creation

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 *cv*;

default constructor.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 *cv*(*Base_curve_2 base*);

constructs curve from the given *base* curve with uninitialized data field.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 *cv*(*Base_curve_2 base*, *Data data*);

constructs curve from the given *base* curve with an attached *data* field.

Access Functions

Curve_data *cv.data()* returns the data field (a non-const version, which returns a reference to the data object, is also available).

void *cv.set_data(Curve_data data)*

sets the data field.

Class Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the curve-data traits extends the *Base_traits_2::X_monotone_curve_2* type with an extra data field.

Inherits From

Base_x_monotone_curve_2

Creation

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 *xcv*;

default constructor.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 *xcv*(*Base_x_monotone_curve_2* *base*)

constructs an *x*-monotone curve from the given *base* curve with uninitialized data field.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 *xcv*(*Base_x_monotone_curve_2* *base*,
X_monotone_curve_data *data*)

constructs an *x*-monotone curve from the given *base x*-monotone curve with an attached *data* field.

Access Functions

X_monotone_curve_data

xcv.data() returns the field (a non-const version, which returns a reference to the data object, is also available).

void *xcv.set_data(X_monotone_curve_data data)*

sets the data field.

CGAL::Arr_consolidated_curve_data_traits_2<Traits,Data>

Definition

The class *Arr_consolidated_curve_data_traits_2*<*Traits*,*Data*> is a model of the *ArrangementTraits_2* concept and serves as a decorator class that allows the extension of the curves defined by the *Traits* parameter, which serves as a geometric traits-class (a model of the *ArrangementTraits_2* concept), with extraneous (non-geometric) data fields of type *Data*.

The traits class inherits its point type from *Traits::Point_2*, and defines an extended *Curve_2* and *X_monotone_curve_2* types, as detailed below.

Each *Curve_2* object is associated with a single data field of type *Data*, and each *X_monotone_curve_2* object is associated with a set of unique data objects. When a curve is subdivided into *x*-monotone subcurves, all these subcurves are associated with a list containing a single data object, copies from the inducing curve. When an *x*-monotone curve is split, its data set is duplicated to both resulting subcurves. In case two (or more) *x*-monotone curves overlap, their data sets are consolidated and are associated with the *x*-monotone curve that represents the overlap.

```
#include <CGAL/Arr_consolidated_curve_data_traits_2.h>
```

Is Model for the Concepts

ArrangementTraits_2

Inherits From

```
Arr_curve_data_traits_2<Traits,
    _Unique_list<Data>,
    _Consolidate_unique_lists<Data>,
    Data>
```

Types

```
typedef Traits          Base_traits_2;          the base traits-class.
typedef typename Base_traits_2::Curve_2
```

```
          Base_curve_2;          the base curve.
typedef typename Base_traits_2::X_monotone_curve_2
```

```
          Base_x_monotone_curve_2;
```

the base *x*-monotone curve.

```
Arr_consolidated_curve_data_traits_2<Traits,Data>:: typedef Data_container
```

a set of data objects that is associated with an *x*-monotone curve.

Arr_consolidated_curve_data_traits_2<Traits,Data>:: typedef Data_iterator

a non-mutable iterator for the data objects in the data container.

Class Arr_consolidated_curve_data_traits_2<Traits,Data>::Data_container

The *Data_container* class nested within the consolidated curve-data traits and associated with the *Traits::X_monotone_curve_2* type is maintained as a list with unique data objects. This representation is simple and efficient in terms of memory consumption. It also requires that the *Data* class supports only the equality operator. Note however that most set operations require linear time.

Creation

Arr_consolidated_curve_data_traits_2<Traits,Data>:: Data_container dset;

default constructor.

Arr_consolidated_curve_data_traits_2<Traits,Data>:: Data_container dset(Data data);

constructs set containing a single *data* object.

Access Functions

<i>std::size_t</i>	<i>dset.size()</i>	returns the number of data objects in the set.
<i>Data_iterator</i>	<i>dset.begin()</i>	returns an iterator pointing to the first data object.
<i>Data_iterator</i>	<i>dset.end()</i>	returns a past-the-end iterator for the data objects.
<i>Data</i>	<i>dset.front()</i>	returns the first data object inserted into the set. <i>Precondition:</i> The number of data objects is not 0.
<i>Data</i>	<i>dset.back()</i>	returns the last data object inserted into the set. <i>Precondition:</i> The number of data objects is not 0.

Predicates

<i>bool</i>	<i>dset == Data_container other</i>	check if the two sets contain the same data objects (regardless of order).
<i>Data_iterator</i>	<i>dset.find(Data data)</i>	find the given <i>data</i> object in the set and returns an iterator for this object, or <i>end()</i> if it is not found.

Modifiers

<i>bool</i>	<i>dset.insert(Data data)</i>	inserts the given <i>data</i> object into the set. Returns <i>true</i> on success, or <i>false</i> if the set already contains the object.
<i>bool</i>	<i>dset.erase(Data data)</i>	erases the given <i>data</i> object from the set. Returns <i>true</i> on success, or <i>false</i> if the set does not contain the object.
<i>void</i>	<i>dset.clear()</i>	clears the set.

ArrangementInputFormatter

A model for the ArrangementInputFormatter concept supports a set of functions that enable reading an arrangement from an input stream using a specific format.

Types

ArrangementInputFormatter::Arrangement_2 the type of arrangement to input.

typedef typename Arrangement_2::Point_2

Point_2; the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the *x*-monotone curve type.

typedef typename Arrangement_2::Size

Size;

typedef typename Arrangement_2::Vertex_handle

Vertex_handle;

typedef typename Arrangement_2::Halfedge_handle

Halfedge_handle;

typedef typename Arrangement_2::Face_handle

Face_handle;

Creation

ArrangementInputFormatter inf; default constructor.

ArrangementInputFormatter inf(std::istream& is);

constructs a formatter that reads from *is*.

void inf.set_in(std::istream& is)

directs *inf* to read from *is*.

Access Functions

std::istream& inf.in()

returns the stream that *inf* reads from.

Precondition: *inf* is directed to a valid output stream.

Formatted Input Functions

<i>void</i>	<i>inf.read_arrangement_begin()</i>	reads a message indicating the beginning of the arrangement.
<i>void</i>	<i>inf.read_arrangement_end()</i>	reads a message indicating the end of the arrangement.
<i>Size</i>	<i>inf.read_size(const char *label = NULL)</i>	reads a size value, which is supposed to be preceeded by the given label.
<i>void</i>	<i>inf.read_vertices_begin()</i>	reads a message indicating the beginning of the vertex records.
<i>void</i>	<i>inf.read_vertices_end()</i>	reads a message indicating the end of the vertex records.
<i>void</i>	<i>inf.read_edges_begin()</i>	reads a message indicating the beginning of the edge records.
<i>void</i>	<i>inf.read_edges_end()</i>	reads a message indicating the end of the edge records.
<i>void</i>	<i>inf.read_faces_begin()</i>	reads a message indicating the beginning of the face records.
<i>void</i>	<i>inf.read_faces_end()</i>	reads a message indicating the end of the face records.
<i>void</i>	<i>inf.read_vertex_begin()</i>	reads a message indicating the beginning of a single vertex record.
<i>void</i>	<i>inf.read_vertex_end()</i>	reads a message indicating the end of a single vertex record.
<i>std::size_t</i>	<i>inf.read_vertex_index()</i>	reads and returns a vertex index.
<i>void</i>	<i>inf.read_point(Point_2& p)</i>	reads a point.

<i>void</i>	<i>inf.read_vertex_data(Vertex_handle v)</i>	reads an auxiliary vertex-data object and associates it with the vertex <i>v</i> .
<i>void</i>	<i>inf.read_edge_begin()</i>	reads a message indicating the beginning of a single edge record.
<i>void</i>	<i>inf.read_edge_end()</i>	reads a message indicating the end of a single edge record.
<i>std::size_t</i>	<i>inf.read_halfedge_index()</i>	reads and returns halfedge index.
<i>void</i>	<i>inf.read_x_monotone_curve(X_monotone_curve_2& c)</i>	reads an <i>x</i> -monotone curve.
<i>void</i>	<i>inf.read_halfedge_data(Halfedge_handle he)</i>	reads an auxiliary halfedge-data object and associates it with the halfedge <i>he</i> .
<i>void</i>	<i>inf.read_face_begin()</i>	reads a message indicating the beginning of a single face record.
<i>void</i>	<i>inf.read_face_end()</i>	reads a message indicating the end of a single face record.
<i>void</i>	<i>inf.read_outer_ccb_begin()</i>	reads a message indicating the beginning of the outer CCB of the current face.
<i>void</i>	<i>inf.read_outer_ccb_end()</i>	reads a message indicating the end of the outer CCB of the current face.
<i>void</i>	<i>inf.read_holes_begin()</i>	reads a message indicating the beginning of the container of holes inside the current face.
<i>void</i>	<i>inf.read_holes_end()</i>	reads a message indicating the end of the container of holes inside the current face.
<i>void</i>	<i>inf.read_inner_ccb_begin()</i>	reads a message indicating the beginning of an inner CCB of the current face.

<i>void</i>	<i>inf.read_inner_ccb_end()</i>	reads a message indicating the end of an inner CCB of the current face.
<i>void</i>	<i>inf.read_ccb_halfedges_begin()</i>	reads a message indicating the beginning a connected component boundary.
<i>void</i>	<i>inf.read_ccb_halfedges_end()</i>	reads a message indicating the end of a connected component boundary.
<i>void</i>	<i>inf.read_isolated_vertices_begin()</i>	reads a message indicating the beginning of the container of isolated vertices inside the current face.
<i>void</i>	<i>inf.read_isolated_vertices_end()</i>	reads a message indicating the end of the container of isolated vertices inside the current face.
<i>void</i>	<i>inf.read_face_data(Face_handle f)</i>	reads an auxiliary face-data object and associates it with the face <i>f</i> .

ArrangementOutputFormatter

A model for the ArrangementOutputFormatter concept supports a set of functions that enable writing an arrangement to an output stream using a specific format.

Types

ArrangementOutputFormatter::Arrangement_2

the type of arrangement to output.

typedef typename Arrangement_2::Point_2

Point_2; the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the *x*-monotone curve type.

typedef typename Arrangement_2::Size

Size;

typedef typename Arrangement_2::Vertex_const_handle

Vertex_const_handle;

typedef typename Arrangement_2::Halfedge_const_handle

Halfedge_const_handle;

typedef typename Arrangement_2::Face_const_handle

Face_const_handle;

Creation

ArrangementOutputFormatter outf; default constructor.

ArrangementOutputFormatter outf(std::ostream& os);

constructs a formatter that writes to *os*.

void outf.set_out(std::ostream& os)

directs *outf* to write to *os*.

Access Functions

std::ostream& *outf.out()* returns the stream that *outf* writes to.
Precondition: outf is directed to a valid output stream.

Formatted Output Functions

void *outf.write_arrangement_begin()*
writes a message indicating the beginning of the arrangement.

void *outf.write_arrangement_end()*
writes a message indicating the end of the arrangement.

void *outf.write_size(const char *label, Size size)*
writes a size value, preceeded by a given label.

void *outf.write_vertices_begin()*
writes a message indicating the beginning of the vertex records.

void *outf.write_vertices_end()*
writes a message indicating the end of the vertex records.

void *outf.write_edges_begin()*
writes a message indicating the beginning of the edge records.

void *outf.write_edges_end()*
writes a message indicating the end of the edge records.

void *outf.write_faces_begin()*
writes a message indicating the beginning of the face records.

void *outf.write_faces_end()*
writes a message indicating the end of the face records.

void *outf.write_vertex_begin()*
writes a message indicating the beginning of a single vertex record.

void *outf.write_vertex_end()*
writes a message indicating the end of a single vertex record.

<i>void</i>	<i>outf.write_vertex_index(std::size_t idx)</i>	writes a vertex index.
<i>void</i>	<i>outf.write_point(Point_2 p)</i>	writes a point.
<i>void</i>	<i>outf.write_vertex_data(Vertex_const_handle v)</i>	writes the auxiliary data associated with the vertex.
<i>void</i>	<i>outf.write_edge_begin()</i>	writes a message indicating the beginning of a single edge record.
<i>void</i>	<i>outf.write_edge_end()</i>	writes a message indicating the end of a single edge record.
<i>void</i>	<i>outf.write_halfedge_index(std::size_t idx)</i>	writes a halfedge index.
<i>void</i>	<i>outf.write_x_monotone_curve(X_monotone_curve_2 c)</i>	writes an <i>x</i> -monotone curve.
<i>void</i>	<i>outf.write_halfedge_data(Halfedge_const_handle he)</i>	writes the auxiliary data associated with the halfedge.
<i>void</i>	<i>outf.write_face_begin()</i>	writes a message indicating the beginning of a single face record.
<i>void</i>	<i>outf.write_face_end()</i>	writes a message indicating the end of a single face record.
<i>void</i>	<i>outf.write_outer_ccb_begin()</i>	writes a message indicating the beginning of the outer CCB of the current face.
<i>void</i>	<i>outf.write_outer_ccb_end()</i>	writes a message indicating the end of the outer CCB of the current face.

<i>void</i>	<i>outf.write_holes_begin()</i>	writes a message indicating the beginning of the container of holes inside the current face.
<i>void</i>	<i>outf.write_holes_end()</i>	writes a message indicating the end of the container of holes inside the current face.
<i>void</i>	<i>outf.write_ccb_halfedges_begin()</i>	writes a message indicating the beginning a connected component's boundary.
<i>void</i>	<i>outf.write_ccb_halfedges_end()</i>	writes a message indicating the end of a connected component's boundary.
<i>void</i>	<i>outf.write_isolated_vertices_begin()</i>	writes a message indicating the beginning of the container of isolated vertices inside the current face.
<i>void</i>	<i>outf.write_isolated_vertices_end()</i>	writes a message indicating the end of the container of isolated vertices inside the current face.
<i>void</i>	<i>outf.write_face_data(Face_const_handle f)</i>	writes the auxiliary data associated with the face.

CGAL::Arr_text_formatter<Arrangement>

Definition

Arr_text_formatter<Arrangement> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an *Arrangement* instance using a simple text format. The arrangement is assumed to store no auxiliary data with its DCEL records (and if there are such records they will not be written or read by the formatter).

The *Arr_text_formatter<Arrangement>* class assumes that the nested *Point_2* and the *Curve_2* types defined by the *Arrangement* template-parameter can both be written to an input stream using the << operator and read from an input stream using the >> operator.

```
#include <CGAL/IO/Arr_text_formatter.h>
```

CGAL::Arr_face_extended_text_formatter<Arrangement>

Definition

Arr_face_extended_text_formatter<Arrangement> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an *Arrangement* instance using a simple text format. The *Arrangement* class should be instantiated with a DCEL class which in turn instantiates the *Arr_face_extended_dcel* template with a *FaceData* type. The formatter supports reading and writing the data objects attached to the arrangement faces as well.

The *Arr_face_extended_text_formatter<Arrangement>* class assumes that the nested *Point_2* and the *Curve_2* types defined by the *Arrangement* template-parameter and that the *FaceData* type can all be written to an input stream using the << operator and read from an input stream using the >> operator.

```
#include <CGAL/IO/Arr_text_formatter.h>

ArrangementPointLocation_2

Definition

A model of the ArrangementPointLocation_2 concept can be attached to an *Arrangement_2* instance and answer point-location queries on this arrangement. Namely, given a *Arrangement_2::Point_2* object, representing a point in the plane, it returns the arrangement cell containing it. In the general case, the query point is contained inside an arrangement face, but in degenerate situations it may lie on an edge or coincide with an arrangement vertex.

Types

ArrangementPointLocation_2::Arrangement_2

the associated arrangement type.

ArrangementPointLocation_2::Point_2

equivalent to *Arrangement_2::Point_2*.

Creation

ArrangementPointLocation_2 pl;

default constructor.

ArrangementPointLocation_2 pl(Arrangement_2 arr);

constructs a point-location object *pl* attached to the given arrangement *arr*.

Query Functions

Object

pl.locate(Point_2 q)

locates the arrangement cell that contains the query point *q* and returns a handle for this cell. The function returns an *Object* instance that wraps either of the following types:

- *Arrangement_2::Face_const_handle*, in case *q* is contained inside an arrangement face;
- *Arrangement_2::Halfedge_const_handle*, in case *q* lies on an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case *q* coincides with an arrangement vertex.

Precondition: *pl* is attached to a valid arrangement instance.

Operations

void *pl.attach(Arrangement_2 arr)*

attaches *pl* to the given arrangement *arr*.

void *pl.detach()*

detaches *pl* from the arrangement it is currently attached to.

ArrangementVerticalRayShoot_2

Definition

A model of the `ArrangementVerticalRayShoot_2` concept can be attached to an `Arrangement_2` instance and answer vertical ray-shooting queries on this arrangement. Namely, given a `Arrangement_2::Point_2` object, representing a point in the plane, it returns the arrangement feature (edge or vertex) that lies strictly above it (or below it). By “strictly” we mean that if the query point lies on an arrangement edge (or on an arrangement vertex) this edge will *not* be the query result, but the feature lying above or below it. (An exception to this rule is the degenerate situation where the query point lies in the interior of a vertical edge.) Note that it may happen that the query point lies above the upper envelope (or below the lower envelope) of the arrangement, so that the vertical ray emanating from it may go to infinity without hitting any arrangement feature on its way. In this case the unbounded face is returned.

Types

`ArrangementVerticalRayShoot_2::Arrangement_2`

the associated arrangement type.

`ArrangementVerticalRayShoot_2::Point_2`

equivalent to `Arrangement_2::Point_2`.

Creation

`ArrangementVerticalRayShoot_2 rs;`

default constructor.

`ArrangementVerticalRayShoot_2 rs(Arrangement_2 arr);`

constructs a ray-shooting object `rs` attached to the given arrangement `arr`.

Query Functions

Object

`rs.ray_shoot_up(Point_2 q)`

locates the arrangement feature that is first hit by an upward-directed vertical ray emanating from the query point q , and returns a handle for this feature. The function returns an *Object* instance that is a wrapper for one of the following types:

- `Arrangement_2::Halfedge_const_handle`, in case the vertical ray hits an arrangement edge;
- `Arrangement_2::Vertex_const_handle`, in case the vertical ray hits an arrangement vertex.
- `Arrangement_2::Face_const_handle` for the unbounded arrangement face, in case q lies above the upper envelope of the arrangement.

Precondition: `rs` is attached to a valid arrangement instance.

Object

rs.ray_shoot_down(Point_2 q)

locates the arrangement feature that is first hit by a downward-directed vertical ray emanating from the query point q , and returns a handle for this feature. The function returns an *Object* instance that is a wrapper for one of the following types:

- *Arrangement_2::Halfedge_const_handle*, in case the vertical ray hits an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case the vertical ray hits an arrangement vertex.
- *Arrangement_2::Face_const_handle* for the unbounded arrangement face, in case q lies below the lower envelope of the arrangement.

Precondition: *rs* is attached to a valid arrangement instance.

Operations

void

rs.attach(Arrangement_2 arr)

attaches *rs* to the given arrangement *arr*.

void

rs.detach()

detaches *rs* from the arrangement it is currently attached to.

Arr_walk_along_a_line_point_location<Arrangement>

Arr_trapezoid_ric_point_location<Arrangement>

Arr_landmarks_point_location<Arrangement,Generator>

CGAL::Arr_naive_point_location<Arrangement>

Definition

The *Arr_naive_point_location<Arrangement>* class implements a naïve algorithm that traverses all the vertices and halfedges in the arrangement in search for an answer to a point-location query. The query time is therefore linear in the complexity of the arrangement. Naturally, this point-location strategy could turn into a heavy time-consuming process when applied to dense arrangements.

```
#include <CGAL/Arr_naive_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_walk_along_line_point_location<Arrangement>

Definition

The *Arr_walk_along_line_point_location<Arrangement>* class implements a very simple point-location (and vertical ray-shooting) strategy that improves the naïve one. The algorithm considers an imaginary vertical ray emanating from the query point, and simulates a walk along the zone of this ray, starting from the unbounded face until reaching the query point. In dense arrangements this walk can considerably reduce the number of traversed arrangement edges, with respect to the naïve algorithm.

The walk-along-a-line point-location object (just like the naïve one) does not use any auxiliary data structures. Thus, attaching it to an existing arrangement takes constant time, and any ongoing updates to this arrangement do not affect the point-location object. It is therefore recommended to use the “walk” point-location strategy for arrangements that are constantly changing, especially if the number of issued queries is not large.

```
#include <CGAL/Arr_walk_along_line_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_trapezoid_ric_point_location<Arrangement>

Definition

The *Arr_trapezoid_ric_point_location<Arrangement>* class implements the incremental randomized algorithm introduced by Mulmuley [Mul90] as presented by Seidel [Sei91] (see also [dBvKOS00, Chapter 6]). It subdivides each arrangement face to pseudo-trapezoidal cells, each of constant complexity, and constructs and maintains a search structure on top of these cells, such that each query can be answered in $O(\log n)$ time, where n is the complexity of the arrangement.

Constructing the search structures takes $O(n \log n)$ time, such that attaching a trapezoidal point-location object to an existing arrangement may incur some overhead in running times. In addition, the point-location object needs to keep its auxiliary data structures up-to-date as the arrangement goes through structural changes. It is therefore recommended to use this point-location strategy for static arrangements (or arrangements that do not alter frequently), and when the number of issued queries is relatively large.

```
#include <CGAL/Arr_trapezoid_ric_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_landmarks_point_location<Arrangement,Generator>

The *Arr_landmarks_point_location*<*Arrangement*,*Generator*> class implements a Jump & Walk algorithm, where special points, referred to as “landmarks”, are chosen in a preprocessing stage, their place in the arrangement is found, and they are inserted into a data-structure that enables efficient nearest-neighbor search (a KD-tree). Given a query point, the nearest landmark is located and a “walk” strategy is applied from the landmark to the query point.

There are various strategies to select the landmark set in the arrangement, where the strategy is determined by the *Generator* template parameter. The following landmark-generator classes are available:

Arr_landmarks_vertices_generator — The arrangement vertices are used as the landmarks set.

Arr_random_landmarks_generator — n random points in the bounding box of the arrangement are chosen as the landmarks set.

Arr_halton_landmarks_generator — n Halton points in the bounding box of the arrangement are chosen as the landmarks set.

Arr_middle_edges_landmarks_generator — The midpoint of each arrangement edge is computed, and the resulting set of points is used as the landmarks set. This generator can be applied only for arrangements of line segments.

Arr_grid_landmarks_generator — A set of n landmarks are chosen on a $\lceil\sqrt{n}\rceil \times \lceil\sqrt{n}\rceil$ grid that covers the bounding box of the arrangement.

The *Arr_landmarks_vertices_generator* class is the default generator and used if no *Generator* parameter is specified.

It is recommended to use the landmarks point-location strategy when the application frequently issues point-location queries on a rather static arrangement that the changes applied to it are mainly insertions of curves and not deletions of them.

```
#include <CGAL/Arr_landmarks_point_location.h>
```

Is Model for the Concepts

ArrangementPointLocation_2

ArrangementVerticalRayShoot_2

CGAL::locate

```
#include <CGAL/Arr_batched_point_location.h>
```

```
template<class Arrangement, class PointsIterator, class OutputIterator>
OutputIterator      locate( Arrangement arr,
                           PointsIterator points_begin,
                           PointsIterator points_end,
                           OutputIterator oi)
```

Performs a batched point-location operation on an arrangement. The function accepts a range of query points, defined by $[points_begin, points_end)$ and locates each point in the arrangement. The query-results are returned in through the output iterator, whose value type is $std::pair<Point_2, Object>$. Namely, each result is given as a point and an object representing the arrangement feature that contains it (an *Object* that may be either *Face_const_handle*, *Halfedge_const_handle* or *Vertex_const_handle*). The result pair in output sequence are sorted by an increasing *xy*-lexicographical order on the query points. The function returns a past-the-end iterator for the output sequence.

Precondition: The value-type of *PointsIterator* is *Traits::Point_2*.

Precondition: The value-type of *OutputIterator* is $std::pair< Traits::Point_2, Object>$.

CGAL::Arr_observer<Arrangement>

Definition

Arr_observer<Arrangement> serves as an abstract base class for all observer classes that are attached to an arrangement instance of type *Arrangement* and receive notifications from the arrangement. This base class handles the attachment of the observer to a given arrangement instance or to the detachment of the observer from this arrangement instance. It also gives a default empty implementation to all notification functions that are invoked by the arrangement to notify the observer on local or global changes it undergoes. The notification functions are all virtual functions, so they can be overridden by the concrete observer classes that inherit from *Arr_observer<Arrangement>*.

In order to implement a concrete arrangement observer-class, one simply needs to derive from *Arr_observer<Arrangement>* and override the relevant notification functions. For example, if only face-split events are of interest, it is sufficient to override just *before_split_face()* (or just *after_split_face()*).

```
#include <CGAL/Arr_observer.h>
```

Types

Arr_observer<Arrangement>::Arrangement_2 the type of the associated arrangement.

```
typedef typename Arrangement_2::Point_2
```

Point_2; the point type.

```
typedef typename Arrangement_2::X_monotone_curve_2
```

X_monotone_curve_2;

the x-monotone curve type.

```
typedef typename Arrangement_2::Vertex_handle
```

Vertex_handle;

```
typedef typename Arrangement_2::Halfedge_handle
```

Halfedge_handle;

```
typedef typename Arrangement_2::Face_handle
```

Face_handle;

```
typedef typename Arrangement_2::Ccb_halfedge_circulator
```

Ccb_halfedge_circulator;

represents the boundary of a connected component (CCB). In particular, holes are represented by a circulator for their outer CCB.

Creation

Arr_observer<Arrangement> *obs*; constructs an observer that is unattached to any arrangement instance.

Arr_observer<Arrangement> *obs*(*Arrangement_2* & *arr*);
constructs an observer and attaches it to the given arrangement *arr*.

Modifiers

void *obs.attach*(*Arrangement_2* & *arr*)
attaches the observer to the given arrangement *arr*.

void *obs.detach*() detaches the observer from its arrangement.

Notifications on Global Arrangement Operations

virtual void *obs.before_assign*(*Arrangement_2* *arr*)
issued just before the attached arrangement is assigned with the contents of another arrangement *arr*.

virtual void *obs.after_assign*() issued immediately after the attached arrangement has been assigned with the contents of another arrangement.

virtual void *obs.before_clear*() issued just before the attached arrangement is cleared.
virtual void *obs.after_clear*(*Face_handle* *uf*)
issued immediately after the attached arrangement has been cleared, so it now consists only of a the unbounded face *uf*.

virtual void *obs.before_global_change*()
issued just before a global function starts to modify the attached arrangement. It is guaranteed that no queries (especially no point-location queries) are issued until the termination of the global function is indicated by *after_global_change*().

virtual void *obs.after_global_change*()
issued immediately after a global function has stopped modifying the attached arrangement.

Notifications on Attachment or Detachment

<i>virtual void</i>	<i>obs.before_attach(Arrangement_2 arr)</i>	issued just before the observer is attached to the arrangement instance <i>arr</i> .
<i>virtual void</i>	<i>obs.after_attach()</i>	issued immediately after the observer has been attached to an arrangement instance.
<i>virtual void</i>	<i>obs.before_detach()</i>	issued just before the observer is detached from its arrangement instance.
<i>virtual void</i>	<i>obs.after_detach()</i>	issued immediately after the observer has been detached from its arrangement instance.

Notifications on Local Changes in the Arrangement

<i>virtual void</i>	<i>obs.before_create_vertex(Point_2 p)</i>	issued just before a new vertex that corresponds to the point <i>p</i> is created.
<i>virtual void</i>	<i>obs.after_create_vertex(Vertex_handle v)</i>	issued immediately after a new vertex <i>v</i> has been created. Note that the vertex still has no incident edges and is not connected to any other vertex.
<i>virtual void</i>	<i>obs.before_create_edge(X_monotone_curve_2 c, Vertex_handle v1, Vertex_handle v2)</i>	issued just before a new edge that corresponds to the <i>x</i> -monotone curve <i>c</i> and connects the vertices <i>v1</i> and <i>v2</i> is created.
<i>virtual void</i>	<i>obs.after_create_edge(Halfedge_handle e)</i>	issued immediately after a new edge <i>e</i> has been created. The halfedge that is sent to this function is always directed from <i>v1</i> to <i>v2</i> (see above).
<i>virtual void</i>	<i>obs.before_modify_vertex(Vertex_handle v, Point_2 p)</i>	issued just before a vertex <i>v</i> is modified to be associated with the point <i>p</i> .
<i>virtual void</i>	<i>obs.after_modify_vertex(Vertex_handle v)</i>	issued immediately after an existing vertex <i>v</i> has been modified.
<i>virtual void</i>	<i>obs.before_modify_edge(Halfedge_handle e, X_monotone_curve_2 c)</i>	issued just before an edge <i>e</i> is modified to be associated with the <i>x</i> -monotone curve <i>c</i> .

<i>virtual void</i>	<i>obs.after_modify_edge(Halfedge_handle e)</i>	issued immediately after an existing edge <i>e</i> has been modified.
<i>virtual void</i>	<i>obs.before_split_edge(Halfedge_handle e, Vertex_handle v, X_monotone_curve_2 c1, X_monotone_curve_2 c2)</i>	issued just before an edge <i>e</i> is split into two edges that should be associated with the <i>x</i> -monotone curves <i>c1</i> and <i>c2</i> . The vertex <i>v</i> corresponds to the split point, and will be used to separate the two resulting edges.
<i>virtual void</i>	<i>obs.after_split_edge(Halfedge_handle e1, Halfedge_handle e2)</i>	issued immediately after an existing edge has been split into the two given edges <i>e1</i> and <i>e2</i> .
<i>virtual void</i>	<i>obs.before_split_face(Face_handle f, Halfedge_handle e)</i>	issued just before a face <i>f</i> is split into two, as a result of the insertion of the edge <i>e</i> into the arrangement.
<i>virtual void</i>	<i>obs.after_split_face(Face_handle f1, Face_handle f2, bool is_hole)</i>	issued immediately after the existing face <i>f1</i> has been split, such that a portion of it now forms a new face <i>f2</i> . The flag <i>is_hole</i> designates whether <i>f2</i> forms a hole inside <i>f1</i> .
<i>virtual void</i>	<i>obs.before_split_hole(Face_handle f, Ccb_halfedge_circulator h, Halfedge_handle e)</i>	issued just before a hole <i>h</i> inside a face <i>f</i> is split into two, as a result of the removal of the edge <i>e</i> from the arrangement.
<i>virtual void</i>	<i>obs.after_split_hole(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2)</i>	issued immediately after a hole inside the face <i>f</i> has been split, resulting in the two holes <i>h1</i> and <i>h2</i> .
<i>virtual void</i>	<i>obs.before_add_hole(Face_handle f, Halfedge_handle e)</i>	issued just before the edge <i>e</i> is inserted as a new hole inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.after_add_hole(Ccb_halfedge_circulator h)</i>	issued immediately after a new hole <i>h</i> has been created. The hole always consists of a single pair of twin halfedges.

<i>virtual void</i>	<i>obs.before_add_isolated_vertex(Face_handle f, Vertex_handle v)</i>	issued just before the vertex <i>v</i> is inserted as an isolated vertex inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.after_add_isolated_vertex(Vertex_handle v)</i>	issued immediately after the vertex <i>v</i> has been set as an isolated vertex.
<i>virtual void</i>	<i>obs.before_merge_edge(Halfedge_handle e1, Halfedge_handle e2, X_monotone_curve_2 c)</i>	issued just before the two edges <i>e1</i> and <i>e2</i> are merged to form a single edge that will be associated with the <i>x</i> -monotone curve <i>c</i> .
<i>virtual void</i>	<i>obs.after_merge_edge(Halfedge_handle e)</i>	issued immediately after two edges have been merged to form the edge <i>e</i> .
<i>virtual void</i>	<i>obs.before_merge_face(Face_handle f1, Face_handle f2, Halfedge_handle e)</i>	issued just before the two edges <i>f1</i> and <i>f2</i> are merged to form a single face, following the removal of the edge <i>e</i> from the arrangement.
<i>virtual void</i>	<i>obs.after_merge_face(Face_handle f)</i>	issued immediately after two faces have been merged to form the face <i>f</i> .
<i>virtual void</i>	<i>obs.before_merge_hole(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2, Halfedge_handle e)</i>	issued just before two holes <i>h1</i> and <i>h2</i> inside the face <i>f</i> are merged to form a single connected component, following the insertion of the edge <i>e</i> into the arrangement.
<i>virtual void</i>	<i>obs.after_merge_hole(Face_handle f, Ccb_halfedge_circulator h)</i>	issued immediately after two holes have been merged to form a single hole <i>h</i> inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.before_move_hole(Face_handle from_f, Face_handle to_f, Ccb_halfedge_circulator h)</i>	issued just before the hole <i>h</i> is moved from one face to another. This can happen if the face <i>to_f</i> containing the hole has just been split from <i>from_f</i> .

<i>virtual void</i>	<i>obs.after_move_hole(Ccb_halfedge_circulator h)</i>	issued immediately after the hole <i>h</i> has been moved to a new face.
<i>virtual void</i>	<i>obs.before_move_isolated_vertex(Face_handle from_f, Face_handle to_f, Vertex_handle v)</i>	issued just before the isolated vertex <i>v</i> is moved from one face to another. This can happen if the face <i>to_f</i> containing the isolated vertex has just been split from <i>from_f</i> .
<i>virtual void</i>	<i>obs.after_move_isolated_vertex(Vertex_handle v)</i>	issued immediately after the isolated vertex <i>v</i> has been moved to a new face.
<i>virtual void</i>	<i>obs.before_remove_vertex(Vertex_handle v)</i>	issued just before the vertex <i>v</i> is removed from arrangement.
<i>virtual void</i>	<i>obs.after_remove_vertex()</i>	issued immediately after a vertex has been removed (and deleted) from the arrangement.
<i>virtual void</i>	<i>obs.before_remove_edge(Halfedge_handle e)</i>	issued just before the edge <i>e</i> is removed from arrangement.
<i>virtual void</i>	<i>obs.after_remove_edge()</i>	issued immediately after an edge has been removed (and deleted) from the arrangement.
<i>virtual void</i>	<i>obs.before_remove_hole(Face_handle f, Ccb_halfedge_circulator h)</i>	issued just before the hole <i>f</i> is removed from inside the face <i>f</i> .
<i>virtual void</i>	<i>obs.after_remove_hole(Face_handle f)</i>	issued immediately after a hole has been removed (and deleted) from inside the face <i>f</i> .

CGAL::Arrangement_with_history_2<Traits,Dcel>

Definition

An object *arr* of the class *Arrangement_with_history_2<Traits,Dcel>* represents the planar subdivision induced by a set of input curves \mathcal{C} . The arrangement is represented as a doubly-connected edge-list (DCEL). As is the case for the *Arrangement_2<Traits,Dcel>*, each DCEL vertex is associated with a point and each edge is associated with an x -monotone curve whose interior is disjoint from all other edges and vertices. Each such x -monotone curve is a subcurve of some $C \in \mathcal{C}$ — or may represent an overlap among several curves in \mathcal{C} .

The *Arrangement_with_history_2<Traits,Dcel>* class-template extends the *Arrangement_2* class-template by keeping an additional container of input curves representing \mathcal{C} , and by maintaining a cross-mapping between these curves and the arrangement edges they induce. This way it is possible to determine the inducing curve(s) of each arrangement edge. This mapping also allows the traversal of input curves, and the traversal of edges induced by each curve.

The *Arrangement_with_history_2<Traits,Dcel>* template has two parameters:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementTraits_2* concept. The traits class defines the *Curve_2* type, which represents an input curve. It also defines the types of x -monotone curves and two-dimensional points, namely *X_monotone_curve_2* and *Point_2*, respectively, and supports basic geometric predicates on them.
- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is by default *Arr_default_dcel<Traits>*.

Self is an abbreviation of the *Arrangement_with_history_2<Traits,Dcel>* type hereafter.

```
#include <CGAL/Arrangement_with_history_2.h>
```

Types

```
Arrangement_with_history_2<Traits,Dcel>:: Traits_2
```

the traits class in use.

```
Arrangement_with_history_2<Traits,Dcel>:: Dcel
```

the DCEL representation of the arrangement.

```
typedef typename Traits_2::Point_2
```

```
Point_2;
```

the point type, as defined by the traits class.

```
typedef typename Traits_2::X_monotone_curve_2
```

```
X_monotone_curve_2;
```

the x -monotone curve type, as defined by the traits class.

typedef typename Traits_2::Curve_2

Curve_2; the curve type, as defined by the traits class.

In addition, the nested types *Vertex*, *Halfedge* and *Face* are defined, as well as all handle, iterator and circulator types, as defined by the *Arrangement_2* class-template (page 1201).

Arrangement_with_history_2<Traits,Dcel>:: Curve_handle

a handle for an input curve.

Arrangement_with_history_2<Traits,Dcel>:: Curve_iterator

a bidirectional iterator over the curves that induce the arrangement. Its value-type is *Curve_2*.

Arrangement_with_history_2<Traits,Dcel>:: Induced_edge_iterator

an iterator over the edges induced by an input curve. Its value type is *Halfedge_handle*.

Arrangement_with_history_2<Traits,Dcel>:: Originating_curve_iterator

an iterator for the curves that originate a given arrangement edge. Its value type is *Curve_handle*.

Creation

Arrangement_with_history_2<Traits,Dcel> arr;

constructs an empty arrangement containing one unbounded face, which corresponds to the whole plane.

Arrangement_with_history_2<Traits,Dcel> arr(Self other);

copy constructor.

*Arrangement_with_history_2<Traits,Dcel> arr(Traits_2 *traits);*

constructs an empty arrangement that uses the given *traits* instance for performing the geometric predicates.

Assignment Methods

Self& *arr = other* assignment operator.

void *arr.assign(Self other)*

assigns the contents of another arrangement.

<i>void</i>	<i>arr.clear()</i>	clears the arrangement.
-------------	--------------------	-------------------------

Access Functions

See the *Arrangement_2* reference pages (page [1201](#)) for the full list.

- Accessing the Input Curves:

<i>Size</i>	<i>arr.number_of_curves()</i>	returns the number of input curves that induce the arrangement.
-------------	-------------------------------	-----------------------------------------------------------------

<i>Curve_iterator</i>	<i>arr.curves_begin()</i>	returns the begin-iterator of the curves inducing the arrangement.
-----------------------	---------------------------	--------------------------------------------------------------------

<i>Curve_iterator</i>	<i>arr.curves_end()</i>	returns the past-the-end iterator of the curves inducing the arrangement.
-----------------------	-------------------------	---------------------------------------------------------------------------

<i>Size</i>	<i>arr.number_of_induced_edges(Curve_handle ch)</i>	returns the number of arrangement edges induced by the curve <i>ch</i> .
-------------	------------------------------------------------------	--------------------------------------------------------------------------

<i>Induced_edge_iterator</i>	<i>arr.induced_edges_begin(Curve_handle ch)</i>	returns the begin-iterator of the edges induced by the curve <i>ch</i> .
------------------------------	--------------------------------------------------	--------------------------------------------------------------------------

<i>Induced_edge_iterator</i>	<i>arr.induced_edges_end(Curve_handle ch)</i>	returns the past-the-end iterator of the edges induced by the curve <i>ch</i> .
------------------------------	------------------------------------------------	---------------------------------------------------------------------------------

<i>Size</i>	<i>arr.number_of_originating_curves(Halfedge_handle e)</i>	returns the number of input curves that originate the edge <i>e</i> .
-------------	-------------------------------------------------------------	-----------------------------------------------------------------------

<i>Originating_curve_iterator</i>	<i>arr.originating_curves_begin(Halfedge_handle e)</i>	returns the begin-iterator of the curves originating the edge <i>e</i> .
-----------------------------------	---------------------------------------------------------	--------------------------------------------------------------------------

<i>Originating_curve_iterator</i>	<i>arr.originating_curves_end(Halfedge_handle e)</i>	returns the past-the-end iterator of the curves originating the edge <i>e</i> .
-----------------------------------	-------------------------------------------------------	---------------------------------------------------------------------------------

Modifiers

See the *Arrangement_2* reference pages (page 1201) for the full list of functions for modifying arrangement vertices.

- *Modifying Arrangement Edges:*

The following functions override their counterparts in the *Arrangement_2* class, as they also maintain the cross-relationships between the input curves and the edges they induce.

Halfedge_handle *arr.split_edge(Halfedge_handle e, Point_2 p)*

splits the edge e into two edges (more precisely, into two halfedge pairs), at a given split point p . The function returns a handle for the halfedge whose source is the same as $e \rightarrow source()$ and whose target vertex is the split point.

Precondition: p lies in the interior of the curve associated with e .

<i>Halfedge_handle</i>	<i>arr.merge_edge(Halfedge_handle e1, Halfedge_handle e2)</i>
------------------------	----------------------------------------------------------------

merges the edges represented by *e1* and *e2* into a single edge. The function returns a handle for one of the merged halfedges.

Precondition: $e1$ and $e2$ share a common end-vertex, of degree 2, and the x -monotone curves associated with $e1$ and $e2$ are mergeable into a single x -monotone curves.

[illegible]

removes the edge e from the arrangement. Since the e may be the only edge incident to its source vertex (or its target vertex), this vertex can be removed as well. The flags *remove_source* and *remove_target* indicate whether the endpoints of e should be removed, or whether they should be left as isolated vertices in the arrangement. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

writes a message indicating the end of the induced edges set.

Has Models

Arr_with_history_text_formatter<*ArrFormatter*> (page [1327](#))

CGAL::Arr_with_history_text_formatter<ArrFormatter>

Definition

Arr_with_history_text_formatter<ArrFormatter> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an arrangement-with-history instance using a simple text format.

The *ArrFormatter* parameter serves as a base class for *Arr_with_history_text_formatter<ArrFormatter>* and must be a model of the *ArrangementInputFormatter* and the *ArrangementOutputFormatter* concepts. It is used to read or write the base arrangement, while the derived class is responsible for reading and writing the set of curves inducing the arrangement and maintaining the relations between these curves and the edges they induce.

Contents

18.1 Introduction	1329
18.1.1 A Simple Program	1329

18.1 Introduction

Let $\mathcal{C} = \{C_1, C_2, \dots, C_n\}$ be a set of curves. We wish to compute all intersection points between two curves in the set in an output-sensitive manner, without having to go over all $O(n^2)$ curve pairs. To this end, we sweep an imaginary line l from $x = -\infty$ to $x = \infty$ over the plane. While sweeping the plane, we keep track of the order of curves intersecting it. This order changes at a finite number of *event points*, such that we only have to calculate the intersection points between two curves when they become contiguous. For more details on the *sweep-line algorithm* see, for example, [dBvKOS00, Chapter 2].

This chapter describes three functions implemented using the sweep-line algorithm: given a collection of input curves, compute all intersection points, compute the set of subcurves that are pairwise interior-disjoint induced by them, and checking whether there is at least one pair of curves among them that intersect in their interior.

The implementation is robust. It supports general curves and handles all degenerate cases, including overlapping curves, vertical segments, and tangency between curves. The robustness of the algorithm is guaranteed if the functions are instantiated with a traits class that employs certified computations. This traits class must be a model of the *ArrangementTraits_2* concept — see the Chapter 17 for more details.

The complexity of the sweep-line algorithm is $O((n+k)\log n)$ where n is the number of the input curves and k is the number of intersection points induced by these curves.

18.1.1 A Simple Program

The simple program listed below computes intersection points induced by a set of four input segments illustrated in figure 18.1.

```

//! \file examples/Arrangement_2/ex_sweep_line.C
// Computing intersection points among curves using the sweep line.

#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Quotient.h>
#include <CGAL/Sweep_line_2_algorithms.h>
#include <list>

typedef CGAL::Quotient<CGAL::MP_Float>      NT;
typedef CGAL::Cartesian<NT>                Kernel;
typedef Kernel::Point_2                     Point_2;
typedef Kernel::Segment_2                   Segment_2;

int main()
{
    // Construct the input segments.
    Segment_2 segments[] = {Segment_2 (Point_2 (1, 5), Point_2 (8, 5)),
                             Segment_2 (Point_2 (1, 1), Point_2 (8, 8)),
                             Segment_2 (Point_2 (3, 1), Point_2 (3, 8)),
                             Segment_2 (Point_2 (8, 5), Point_2 (8, 8))};

    // Compute all intersection points.
    std::list<Point_2>      pts;

    CGAL::get_intersection_points (segments, segments + 4,
                                   std::back_inserter (pts));

    // Print the result.
    std::copy (pts.begin(), pts.end(),
               std::ostream_iterator<Point_2>(std::cout, "\n"));

    return (0);
}

```

Design and Implementation History

The current version of the sweep-line algorithm was written by Baruch Zukerman, based on previous implementations by Ester Ezra and Tali Zvi.

2D Intersection of Curves

Reference Manual

Baruch Zukerman and Ron Wein

This chapter describes three functions implemented using the sweep-line algorithm: given a collection \mathcal{C} of planar curves, compute all intersection points among them, obtain the set of maximal pairwise interior-disjoint subcurves of the curves in \mathcal{C} , or check whether there is at least one pair of curves in \mathcal{C} that intersect in their interior.

The first two operations are performed in an output-sensitive manner.

CGAL::get_intersection_points

```
#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      get_intersection_points( InputIterator curves_begin,
                                           InputIterator curves_end,
                                           OutputIterator points,
                                           bool report_endpoints = false,
                                           Traits traits = Default_traits())
```

given a range of curves, compute all intersection points between two (or more) input curves. If the flag *report_endpoints* is *true*, then the curve endpoints are reported as well. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::Point_2*. The output points are reported in an increasing *xy*-lexicographical order.

CGAL::get_subcurves

```
#include <CGAL/Sweep_line_2_algorithms.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      get_subcurves( InputIterator curves_begin,
                                   InputIterator curves_end,
                                   OutputIterator subcurves,
                                   bool multiple_overlaps = false,
                                   Traits traits = Default_traits())
```

given a range of curves, compute all x -monotone subcurves that are pairwise disjoint in their interior, as induced by the input curves. If the flag *multiple_overlaps* is *true*, then a subcurve that represents an overlap of k input curves is reported k times; otherwise, each subcurve is reported only once. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::X_monotone_curve_2*.

CGAL::do_curves_intersect

```
#include <CGAL/Sweep_line_2_algorithms.h>
```

```
template <class InputIterator, class Traits>  
bool do_curves_intersect( InputIterator curves_begin,  
                          InputIterator curves_end,  
                          Traits traits = Default_traits())
```

given a range of curves, check whether there is at least one pair of curves that intersect in their interior. The function returns *true* if such a pair is found, and *false* if all curves are pairwise disjoint in their interior. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*.

19.1 Introduction

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

Figure 19.1: An arrangement of segments before (a) and after (b) SR (hot pixels are shaded)

19.2 What is Snap Rounding/Iterated Snap Rounding

Given a finite collection S of segments in the plane, the arrangement of S denoted $\mathcal{A}(S)$ is the subdivision of the plane into vertices, edges, and faces induced by S . A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, the SR procedure `snap_rounding_2<Traits,InputIterator,OutputContainer>` proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e , in the same order as they are met by e . Figure 19.1 demonstrates the results of SR.

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. Figure 19.2 depicts the results of SR and ISR on the same input. Conceptually, the ISR procedure is equivalent to repeated application of SR, namely we apply SR to the original set of segments, then we use the output of SR as input to another round of SR and so on until all the vertices are well separated from non-incident edges. Algorithmically we operate differently, as this repeated application of SR would have resulted in an efficient overall process. The algorithmic details are given in [HP02].

19.3 Terms and Software Design

Our package supports both schemes, implementing the algorithm described in [HP02]. Although the paper only describes an algorithm for ISR, it is easy to derive an algorithm for SR, by performing only the first rounding level for each segment.

The input to the program is a set S of n segments, $S = \{s_1, \dots, s_n\}$ and the output is a set G of n polylines, with a polyline g_i for each input segments s_i . An input segment is given by the coordinates of its endpoints. An output polyline is given by the ordered set of vertices v_0, \dots, v_k along the polyline. The polyline consists of the segments $(v_0v_1), \dots, (v_{k-1}v_k)$.

There are three template parameters: *Traits* is the underlying geometry, i.e., the number type used and the coordinate representation. *InputIterator* is the type of the iterators that point to the first and after-the-last elements of the input. Finally, *OutputContainer* is the type of the output container.

Since the algorithm requires kernel functionalities such as the rounding to the center of a pixel, a special traits class must be provided. The precise description of the requirements is given by the concept `SnapRoundingTraits_2`. The class `Snap_rounding_traits_2` is a model of this concept.

19.4 Four Line Segment Example

The following example generates an ISR representation of an arrangement of four line segments. In particular it produces a list of points that are the vertices of the resulting polylines in a plane tiled with one-unit square pixels.

```
#include <CGAL/basic.h>
```

Figure 19.2: An arrangement of segments before (a), after SR (b) and ISR (c) (hot pixels are shaded).

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Snap_rounding_traits_2.h>
#include <CGAL/Snap_rounding_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>          Number_type;
typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Snap_rounding_traits_2<Kernel>    Traits;
typedef Kernel::Segment_2                      Segment_2;
typedef Kernel::Point_2                       Point_2;
typedef std::list<Segment_2>                   Segment_list_2;
typedef std::list<Point_2>                     Polyline_2;
typedef std::list<Polyline_2>                  Polyline_list_2;

int main()
{
    Segment_list_2 seg_list;
    Polyline_list_2 output_list;

    seg_list.push_back(Segment_2(Point_2(0, 0), Point_2(10, 10)));
    seg_list.push_back(Segment_2(Point_2(0, 10), Point_2(10, 0)));
    seg_list.push_back(Segment_2(Point_2(3, 0), Point_2(3, 10)));
    seg_list.push_back(Segment_2(Point_2(7, 0), Point_2(7, 10)));

    // Generate an iterated snap-rounding representation, where the centers of
    // the hot pixels bear their original coordinates, using 5 kd trees:
    CGAL::snap_rounding_2<Traits, Segment_list_2::const_iterator, Polyline_list_2>
        (seg_list.begin(), seg_list.end(), output_list, 1.0);

    int counter = 0;
    Polyline_list_2::const_iterator iter1;
    for (iter1 = output_list.begin(); iter1 != output_list.end(); ++iter1) {
        std::cout << "Polyline number " << ++counter << ":\n";
        Polyline_2::const_iterator iter2;
        for (iter2 = iter1->begin(); iter2 != iter1->end(); ++iter2)
```

```

        std::cout << "      (" << iter2->x() << ":" << iter2->y() << ")\n";
    }

    return(0);
}

```

This program generates four polylines, one for each input segment. The exact output follows:

Polyline number 1:

```

(0/4:0/4)
(12/4:12/4)
(20/4:20/4)
(28/4:28/4)
(40/4:40/4)

```

Polyline number 2:

```

(0/4:40/4)
(12/4:28/4)
(20/4:20/4)
(28/4:12/4)
(40/4:0/4)

```

Polyline number 3:

```

(12/4:0/4)
(12/4:12/4)
(12/4:28/4)
(12/4:40/4)

```

Polyline number 4:

```

(28/4:0/4)
(28/4:12/4)
(28/4:28/4)
(28/4:40/4)

```

The package is supplied with a graphical demo program that opens a window, allows the user to edit segments dynamically, applies a selected snap-rounding procedures, and displays the result onto the same window (see `<CGAL_ROOT>/demo/Snap_rounding_2/demo.C`).

2D Snap Rounding Reference Manual

CGAL::snap_rounding_2

Definition

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

Given a finite collection \mathcal{S} of segments in the plane, the arrangement of \mathcal{S} denoted $\mathcal{A}(\mathcal{S})$ is the subdivision of the plane into vertices, edges, and faces induced by \mathcal{S} . A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, SR proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e , in the same order as they are met by e .

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. For more details on ISR see [HP02].

The traits used here must support (arbitrary-precision) rational number type as this is a basic requirement of SR.

```
#include <CGAL/Snap_rounding_2.h>
```

```
template < class Traits, class InputIterator, class OutputContainer >
void      snap_rounding_2( InputIterator begin,
                           InputIterator end,
                           OutputContainer& output_container,
                           typename Traits::FT pixel_size,
                           bool do_isr = true,
                           bool int_output = true,
                           unsigned int number_of_kd_trees = 1)
```

The first two parameters denote the first and after-the-last iterators of the input segments. The third parameter is a reference to a container of the output polylines. Since a polyline is composed of a sequence of points, a polyline is a container itself. The fifth parameter determines whether to apply ISR or SR.

The forth parameter denotes the pixel size w . The plane will be tiled with square pixels of width w such that the origin is the center of a pixel. The sixth parameter denotes the output representation. If the value of the sixth parameter is *true* then the centers of pixels constitute the integer grid, and hence the vertices of the output polylines will be integers. For example, the coordinates of the center of the pixel to the right of the pixel containing the origin will be $(1,0)$ regardless of the pixel width. If the value of the sixth parameter is *false*, then the centers of hot pixels (and hence the vertices of the output polylines) will bear their original coordinates, which may not necessarily be integers. In the latter case, the coordinates of the center of the pixel to the right of the pixel containing the origin, for example, will be $(w,0)$.

The seventh (and last) parameter is briefly described next; for a detailed description see [HP02].

A basic query used in the algorithm is to report the hot pixels of size w that a certain segment s intersects. An alternative way to do the same is to query the hot pixels' centers contained in a Minkowski sum of s with a pixel of width w centered at the origin; we denote this Minkowski sum by $M(s)$. Since efficiently implementing this kind of query is difficult, we use an orthogonal range-search structure instead. We query with the bounding box $B(M(s))$ of $M(s)$ in a two-dimensional kd-tree which stores the centers of hot pixels. Since $B(M(s))$ in general is larger than $M(s)$, we still need to filter out the hot pixels which do not intersect s .

While this approach is easy to implement with CGAL, it may incur considerable overhead since the area of $B(M(s))$ may be much larger than the area of $M(s)$, possibly resulting in many redundant hot pixels to filter out. Our heuristic solution, which we describe next, is to use a cluster of kd-trees rather than just one. The cluster includes several kd-trees, each has the plane, and hence the centers of hot pixels, rotated by a different angle in the first quadrant of the plane; for our purpose, a rotation by angles outside this quadrant is symmetric to a rotation by an angle in the first quadrant.

Given a parameter c , the angles of rotation are $(i-1)\frac{\pi}{2c}$, $i = 1, \dots, c$, and we construct a kd-tree corresponding to each of these angles. Then for a query segment s , we choose the kd-tree for which the area of $B(M(s))$ is the smallest, in order to (potentially) get less hot pixels to filter out. Since constructing many kd-trees may be costly, our algorithm avoids building a kd-tree which it expects to be queried a relatively small number of times (we estimate this number in advance). How many kd-trees should be used? It is difficult to provide a simple answer for that. There are inputs for which the time to build more than one kd-tree is far greater than the time saved by having to filter out less hot pixels (sparse arrangements demonstrate this behavior), and there are inputs which benefit from using several kd-trees. Thus, the user can control the number of kd-trees with the parameter *number_of_kd_trees*. Typically, but not always, one kd-tree (the default) is sufficient.

Precondition: *pixel_size* must have a positive value and *number_of_kd_trees* must be a positive integer.

SnapRoundingTraits_2

Definition

The concept `SnapRoundingTraits_2` lists the set of requirements that must be fulfilled by an instance of the *Traits* template-parameter of the function `snap_rounding_2<Traits, InputIterator, OutputContainer>()`. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

Refines

This concept refines the standard concepts `DefaultConstructible`, `Assignable` and `CopyConstructible`. It also refines the concept `SweepLineTraits_2` (page ??). An instance of this concept is used as the traits class for the `Sweep_line_2.get_intersection_points()` operation. The requirements listed below are induced by components of the `snap_rounding_2()` function other than the call to `Sweep_line_2.get_intersection_points()`. Naturally, some of them may already be listed in `SweepLineTraits_2`.

Types

<code>SnapRoundingTraits_2:: FT</code>	The number type. This type must fulfill the requirements on <i>FieldNumberType</i>
<code>SnapRoundingTraits_2:: Point_2</code>	The point type.
<code>SnapRoundingTraits_2:: Segment_2</code>	The segment type.
<code>SnapRoundingTraits_2:: Iso_rectangle_2</code>	The iso-rectangle type.
<code>SnapRoundingTraits_2:: Construct_vertex_2</code>	Function object. Must provide the operator <i>Point_2 operator()(Segment_2 seg, int i)</i> , which returns the source or target of <i>seg</i> . If <i>i</i> modulo 2 is 0, the source is returned, otherwise the target is returned.
<code>SnapRoundingTraits_2:: Construct_segment_2</code>	Function object. Must provide the operator <i>Segment_2 operator()(Point_2 p, Point_2 q)</i> , which introduces a segment with source <i>p</i> and target <i>q</i> . The segment is directed from the source towards the target.
<code>SnapRoundingTraits_2:: Construct_iso_rectangle_2</code>	Function object. Must provide the operator <i>Iso_rectangle_2 operator()(Point_2 left, Point_2 right, Point_2 bottom, Point_2 top)</i> , which introduces an iso-oriented rectangle for whose minimal <i>x</i> coordinate is the one of <i>left</i> , the maximal <i>x</i> coordinate is the one of <i>right</i> , the minimal <i>y</i> coordinate is the one of <i>bottom</i> , the maximal <i>y</i> coordinate is the one of <i>top</i> .
<code>SnapRoundingTraits_2:: To_double</code>	Function object. Must provide the operator <i>double operator()(FT)</i> , which computes an approximation of a given number of type <i>FT</i> . The precision of this operation is of not high significance, as it is only used in the implementation of the heuristic technique to exploit a cluster of kd-trees rather than just one.

<i>SnapRoundingTraits_2:: Compare_x_2</i>	Function object. Must provide the operator <i>Comparison_result operator()(Point_2 p, Point_2 q)</i> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>x</i> -ordering of points <i>p</i> and <i>q</i> .
<i>SnapRoundingTraits_2:: Compare_y_2</i>	Function object. Must provide the operator <i>Comparison_result operator()(Point_2 p, Point_2 q)</i> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>y</i> -ordering of points <i>p</i> and <i>q</i> .
<i>SnapRoundingTraits_2:: Snap_2</i>	Rounds a point to a center of a pixel (unit square) in the grid used by the Snap Rounding algorithm. Note that no conversion to an integer grid is done yet. Must have the syntax <i>void operator()(Point_2 p, FT pixel_size, FT &x, FT &y)</i> where <i>p</i> is the input point, <i>pixel_size</i> is the size of the pixel of the grid, and <i>x</i> and <i>y</i> are the <i>x</i> and <i>y</i> -coordinates of the rounded point respectively.
<i>SnapRoundingTraits_2:: Integer_grid_point_2</i>	Convert coordinates into an integer representation where one unit is equal to pixel size. For instance, if a point has the coordinates (3.7, 5.3) and the pixel size is 0.5, then the new point will have the coordinates of (7, 10). Note, however, that the number type remains the same here, although integers are represented. Must have the syntax <i>Point_2 operator()(Point_2 p, NT pixel_size)</i> where <i>p</i> is the converted point and <i>pixel_size</i> is the size of the pixel of the grid.
<i>SnapRoundingTraits_2:: Minkowski_sum_with_pixel_2</i>	Returns the vertices of a polygon, which is the Minkowski sum of a segment and a square centered at the origin with edge size <i>pixel edge</i> . Must have the syntax <i>void operator()(std::list<Point_2>& vertices_list, Segment_2 s, NT unit_square)</i> where <i>vertices_list</i> is the list of the vertices of the Minkowski sum polygon, <i>s</i> is the input segment and <i>unit_square</i> is the edge size of the pixel.

Creation

This concept refines the standard concepts `DefaultConstructible`, `Assignable` and `CopyConstructible`.

Operations

The following functions construct the required function objects occasionally referred as functors listed above.

<i>Construct_vertex_2</i>	<i>traits.construct_vertex_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_iso_rectangle_2</i>	<i>traits.construct_iso_rectangle_2_object()</i>
<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Snap_2</i>	<i>traits.snap_2_object()</i>
<i>Integer_grid_point_2</i>	<i>traits.integer_grid_point_2_object()</i>
<i>Minkowski_sum_with_pixel_2</i>	<i>traits.minkowski_sum_with_pixel_2_object()</i>

Has Models

CGAL::Snap_rounding_traits<*Kernel*>

See Also

CGAL::Snap_rounding_2<*Traits*>

CGAL::Snap_rounding_traits_2<Kernel>

The class *Snap_rounding_traits_2<Kernel>* is a model of the *SnapRoundingTraits_2* concept, and is the only traits class supplied with the package. This class should be instantiated with an exact geometric kernel that conforms to the CGAL kernel-concept, such as the *Cartesian<gmpq>* kernel.

This geometric kernel must provide an (arbitrary-precision) rational number type (*FT*), *Point_2*, *Segment_2* and *Iso_rectangle_2*. It should be possible to cast numbers of the number type *FT* to double-precision representation. That is, the function *CGAL::to_double(FT)* must be supported.

The *CGAL::to_double()* function is used to implement the operation that rounds the coordinates of a point to a center of a pixel. This operation is one of the traits-concept requirement. The coordinates are converted to double, rounded down to the nearest grid point, and finally adjusted to lie on a center of a pixel. Notice that if *CGAL::to_double()* returns the closet value, then when it rounds up a given coordinate, the resulting ISR, may be imprecise, and the distance between some vertex and a non-incident edge can be slightly less than the guaranteed half-the width-of-a-pixel.

This chapter describes the two dimensional triangulations of CGAL. Section 20.1 recalls the main definitions about triangulations. Sections 20.2 discusses the way two-dimensional triangulations are represented in CGAL. Section 20.3 presents the overall software design of the 2D triangulations package. The next sections present the different two dimensional triangulations classes available in CGAL : basic triangulations (section 20.4), Delaunay triangulations (Section 20.5), regular triangulations (Section 20.6), constrained triangulations (Section 20.7), and constrained Delaunay triangulations (Section 20.8). Section 20.9 describes a class which implements a constrained or constrained Delaunay triangulation with an additional data structure to describe how the constraints are refined by the edges of the triangulations. Section 20.10 describes a hierarchical data structure for fast point location queries. At last, Section 20.11 explains how the user can benefit from the flexibility of CGAL triangulations using customized classes for faces and vertices.

20.1 Definitions

A two dimensional triangulation can be roughly described as a set T of triangular facets such that :

- two facets either are disjoint or share a lower dimensional face (edge or vertex).
- the set of facets in T is connected for the adjacency relation.
- the domain U_T which is the union of facets in T has no singularity.

More precisely, a triangulation can be described as a simplicial complex. Let us first record a few definitions.

A simplicial complex is a set T of simplices such that

- any face of a simplex in T is a simplex in T
- two simplices in T either are disjoint or share a common subspace.

The dimension d of a simplicial complex is the maximal dimension of its simplices.

A simplicial complex T is pure if any simplex of T is included in a simplex of T with maximal dimension.

Two simplices in T with maximal dimension d are said to be adjacent if they share a $(d - 1)$ dimensional subspace. A simplicial complex is connected if the adjacency relation defines a connected graph over the set of simplices of T with maximal dimension.

The union U_T of all simplices in T is called the domain of T . A point p in the domain of T is said to singular if its surrounding in U_T is neither a topological ball nor a topological disc.

Then, a two dimensional triangulation can be described as a two dimensional simplicial complex that is pure, connected and without singularity.

Each facet of a triangulation can be given an orientation which in turn induces an orientation on the edges incident to that facet. The orientation of two adjacent facets are said to be consistent if they induce opposite orientations on their common incident edge. A triangulation is said to be orientable if the orientation of each facet can be chosen in such a way that all pairs of incident facets have consistent orientations.

The data structure underlying CGAL triangulations allows to represent the combinatorics of any orientable two dimensional triangulations without boundaries. On top of this data structure, the 2D triangulations classes take care of the geometric embedding of the triangulation and are designed to handle planar triangulations. The plane of the triangulation may be embedded in a higher dimensional space.

The triangulations of CGAL are complete triangulations which means that their domain is the convex hull of their vertices. Because any planar triangulation can be completed, this is not a real restriction. For instance, a triangulation of a polygonal region can be constructed and represented as a subset of a constrained triangulation in which the region boundary edges have been input as constrained edges (see Section 20.7, 20.8 and 20.9).

Strictly speaking, the term *face* should be used to design a face of any dimension, and the two-dimensional faces of a triangulation should be properly called *facets*. However, following a common usage, we hereafter often call *faces*, the facets of a two dimensional triangulation.

20.2 Representation

The set of faces

A 2D triangulation of CGAL can be viewed as a planar partition whose bounded faces are triangular and cover the convex hull of the set of vertices. The single unbounded face of this partition is the complementary of the convex hull. In many applications, such as Kirkpatrick's hierarchy or incremental Delaunay construction, it is convenient to deal with only triangular faces. Therefore, a fictitious vertex, called the *infinite vertex* is added to the triangulation as well as *infinite edges* and *infinite faces* incident to it.. Each infinite edge is incident to the infinite vertex and to a vertex of the convex hull. Each infinite face is incident to the infinite vertex and to a convex hull edge.

Therefore, each edge of the triangulation is incident to exactly two faces and the set of faces of a triangulation is topologically equivalent to a two-dimensional sphere. This extends to lower dimensional triangulations arising in degenerate cases or when the triangulations as less than three vertices. Including the infinite faces, a one dimensional triangulation is a ring of edges and vertices topologically equivalent to a 1-sphere. A zero dimensional triangulation, whose domain is reduced to a single point, is represented by two vertices that is topologically equivalent to a 0-sphere.

Note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it nor on an infinite face.

A representation based on faces and vertices

Because a triangulation is a set of triangular faces with constant-size complexity, triangulations are not implemented as a layer on top of a planar map. CGAL uses a proper internal representation of triangulations based on faces and vertices rather than on edges. Such a representation saves storage space and results in faster algorithms [BDTY00].

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

Figure 20.1: Infinite vertex and infinite faces

Figure 20.2: Vertices and neighbors.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 20.2, the functions $ccw(i)$ and $cw(i)$ shown on this figure compute respectively $i + 1$ and $i - 1$ modulo 3.

The edges are not explicitly represented, they are only implicitly represented through the adjacency relations of two faces. Each edge has two implicit representations : the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f .

20.3 Software Design

The triangulations classes of CGAL provide high-level geometric functionalities such as location of a point in the triangulation, insertion or removal of a point. They are build as a layer on top of a data structure called the triangulation data structure. The triangulation data structure can be thought of as a container for the faces and vertices of the triangulation. This data structure also takes care of all the combinatorial aspects of the triangulation.

This separation between the geometric aspect and the combinatorial part is reflected in the software design by the fact that the triangulation classes have two template parameters :

- the first parameter stands for a **geometric traits** class providing the geometric primitives (points, segments

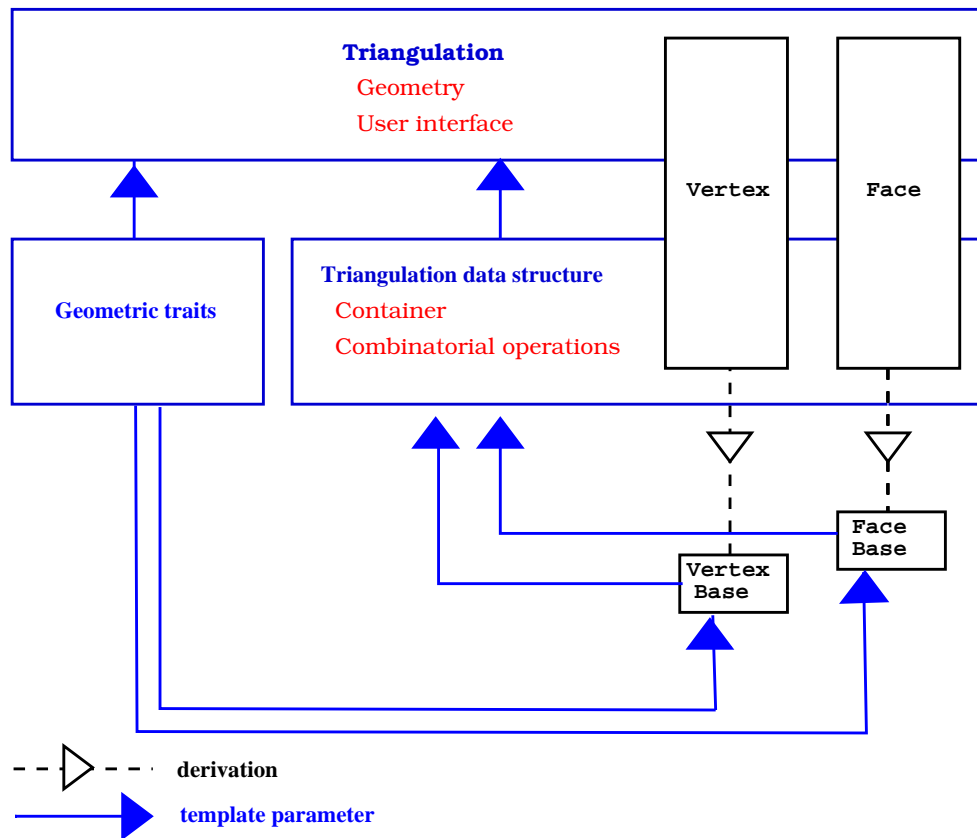

Figure 20.3: The triangulations software design.

and triangles) of the triangulation and the elementary operations (predicate or constructions) on those objects.

- the second parameter stands for a **triangulation data structure** class. The concept of triangulation data structure is described in Section 21.2 of Chapter 21. The triangulation data structure defines the types used to represent the faces and vertices of the triangulation, as well as additional types (handles, iterators and circulators) to access and visit the faces and vertices.

CGAL provides the class *Triangulation_data_structure_2*<*Vb*,*Fb*> as a default model of triangulation data structure. The class *Triangulation_data_structure_2*<*Vb*,*Fb*> has two template parameters standing for a vertex class and a face class. CGAL defines concepts for these template parameters and provide default models for these concepts. The vertex and base classes are templated by the geometric traits which allows them to have some knowledge of the geometric primitives of the triangulation. Those default vertex and face base classes can be replaced by user customized base classes in order, for example, to deal with additional properties attached to the vertices or faces of a triangulation. See section 20.11 for more details on the way to make use of this flexibility.

The Figure 20.3 summarizes the design of the triangulation package, showing the three layers (base classes, triangulation data structure and triangulation) forming this design.

The top triangulation level, responsible for the geometric embedding of the triangulation comes in different flavors according to the different kind of triangulations: basic, Delaunay, regular, constrained or constrained Delaunay. Each kind of triangulations correspond to a different class. Figure 20.4 summarizes the derivation dependencies of CGAL 2D triangulations classes. Any 2D triangulation class is parametrized by a geometric

Figure 20.4: The derivation tree of 2D triangulations.

traits and a triangulation data structure. While a unique concept *TriangulationDataStructure_2* describes the triangulation data structure requirements for any triangulation class, the concept of geometric traits actually depends on the triangulation class. In general, the requirements for the vertex and face base classes are described by the basic concepts *TriangulationVertexBase_2* and *TriangulationFaceBase_2*. However, some triangulation classes requires base classes implementing refinements of the basic concepts.

20.4 Basic Triangulations

20.4.1 Description

The class *Triangulation_2*<*Traits*,*Tds*> serves as a base class for the other 2D triangulations classes and implements the user interface to a triangulation.

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a model of the concept *Handle* which basically offers the two dereference operators * and -> . A circulator is a type devoted to visit circular sequences. Handles are used whenever the accessed element is not part of a sequence. Iterators and circulators are used to visit all or parts of the triangulation.

The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to the handles with the same value type, so that when calling a member function, any handle type argument can be replaced by an iterator or a circulator with the same value type.

The triangulation class allows to visit the vertices and neighbors of a face in clockwise or counterclockwise order.

There are circulators to visit the edges or faces incident to a given vertex or the vertices adjacent to it. Another circulator type allows to visit all the faces traversed by a given line. Circulators step through infinite features as well as through finite ones.

The triangulation class offers some iterators to visit all the faces, edges or vertices and also iterators to visit selectively the finite faces, edges or vertices.

Figure 20.5: Flip.

Figure 20.6: Flip.

The triangulation class provides methods to test the infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face) given its vertices.

The triangulation class provides a method to locate a given point with respect to a triangulation. In particular, this method reports whether the point coincides with a vertex of the triangulation, lies on an edge, in a face or outside of the convex hull. In case of a degenerate lower dimensional triangulation, the query point may also lie outside the triangulation affine hull.

The triangulation class also provides methods to locate a point with respect to a given finite face of the triangulation or with respect to its circumcircle. The faces of the triangulation and their circumcircles have the counterclockwise orientation.

The triangulation can be modified by several functions : insertion of a point, removal of a vertex, flipping of an edge. The flipping of an edge is possible when the union of the two incident faces forms a convex quadrilateral (see Figure 20.6).

Implementation

Locate is implemented by a line walk. The walk begins at a vertex of the face which is given as an optional argument or at an arbitrary vertex of the triangulation if no optional argument is given. It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random. The class *Triangulation_hierarchy_2*<Traits,Tds>, described in section 20.10, implements a data structure designed to offer an alternate more efficient point location algorithm.

Insertion of a point is done by locating a face that contains the point, and splitting this face into three new faces. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and retriangulating the hole. Removal takes a time at most proportionnal to d^2 , where d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

Geometric Traits

The geometric traits of a triangulation is required to provide the geometric objects (points, segments and triangles) building up the triangulation together with the geometric predicates on those objects. The required predicates are:

- comparison of the x or y coordinates of two points.
- the orientation test which computes the order type of three given point.

The concept *TriangulationTraits_2* describes the requirements for the geometric traits class of a triangulation. The CGAL kernel classes are models for this concept. The CGAL library also provides dedicated models of *TriangulationTraits_2* using the kernel geometric objects and predicates. These classes are themselves templated with a CGAL kernel and extract the required types and predicates from the kernel. The traits class *Triangulation_euclidean_traits_2<R>* is designed to deal with ordinary two dimensional points. The class *Triangulation_euclidean_traits_xy_3<R>* is a geometric traits class to build the triangulation of a terrain. Such a triangulation is a two-dimensional triangulation embedded in three dimensional space. The data points are three-dimensional points. The triangulation is build according to the projections of those points on the xy plane and then lifted up to the original three-dimensional data points. This is especially usefull to deal with GIS terrains. Instead of really projecting the three-dimensional points and maintaining a mapping between each point and its projection (which costs space and is error prone), the traits class supplies geometric predicates that ignore the z -coordinates of the points. See Section 20.5 for an example. CGAL provides also the geometric traits classes *Triangulation_euclidean_traits_yz_3<R>* and *Triangulation_euclidean_traits_zx_3<R>* to deal with projections on the xz plane and yz -plane, respectively.

20.4.2 Example of a Basic Triangulation

The following program creates a triangulation of 2D points using the default kernel *Exact_predicate_inexact_constructions_kernel* as geometric traits and the default triangulation data structure. The input points are read from a file and inserted in the triangulation. Finally points on the convex hull are written to `cout`.

```
// file: examples/Triangulation_2/triangulation_prog1.C

#include <fstream>

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_2<K>          Triangulation;
typedef Triangulation::Vertex_circulator Vertex_circulator;
typedef Triangulation::Point             Point;

int main() {
    std::ifstream in("data/triangulation_prog1.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;

    Triangulation t;
    t.insert(begin, end);

    Vertex_circulator vc = t.incident_vertices(t.infinite_vertex()),
        done(vc);
```

```

if (vc != 0) {
    do { std::cout << vc->point() << std::endl;
        }while(++vc != done);
    }
    return 0;
}

```

20.5 Delaunay Triangulations

20.5.1 Description

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> is designed to represent the Delaunay triangulation of a set of data points in the plane. A Delaunay triangulation fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no data point in its interior. For a point set with no subset of four cocircular points the Delaunay triangulation is unique, it is dual to the Voronoi diagram of the set of points.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> derives from the class *Triangulation_2*<*Traits*,*Tds*>.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> inherits the types defined by the basic class *Triangulation_2*<*Traits*,*Tds*>. Additional types, provided by the traits class, are defined to represent the dual Voronoi diagram.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> overwrites the member functions that insert a new point in the triangulation or remove a vertex from it to maintain the Delaunay property. It also has a member function (*Vertex_handle nearest_vertex(const Point& p)*) to answer nearest neighbor queries and member functions to construct the elements (vertices and edges) of the dual Voronoi diagram.

Geometric traits

The geometric traits has to be a model of the concept *DelaunayTriangulationTraits_2* which refines the concept *TriangulationTraits_2*. In particular this concept provides the *side_of_oriented_circle* predicate which, given four points *p, q, r, s* decides the position of the point *s* with respect to the circle passing through *p, q* and *r*. The *side_of_oriented_circle* predicate actually defines the Delaunay triangulation. Changing this predicate allows to build variant of Delaunay triangulations for different metrics such that L_1 or L_∞ metric or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points.

The CGAL kernel classes and the class *Triangulation_euclidean_traits_2*<*R*> are models of the concept *DelaunayTriangulationTraits_2* for the euclidean metric. The traits class for terrains, *Triangulation_euclidean_traits_xy_3*<*R*>,

Triangulation_euclidean_traits_yz_3<*R*>, and

Triangulation_euclidean_traits_zx_3<*R*>

are also models of *DelaunayTriangulationTraits_2* except that they do not fulfill the requirements for the duality functions and nearest vertex queries.

Implementation

The insertion of a new point in the Delaunay triangulation is performed using first the insertion member function of the basic triangulation and second performing a sequence of flips to restore the Delaunay property. The

number of flips that have to be performed is $O(d)$ if the new vertex has degree d in the updated Delaunay triangulation. For points distributed uniformly at random, each insertion takes time $O(1)$ on average, once the point has been located in the triangulation.

Removal calls the removal in the triangulation and then retriangulates the hole created in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation.

After having performed a point location, the nearest neighbor of a point is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

20.5.2 Example : a Delaunay Terrain

The following code creates a Delaunay triangulation with the usual Euclidean metric for the vertical projection of a terrain model. The points have elevation, that is they are 3D points, but the predicates used to build the Delaunay triangulation are computed using only the x and y coordinates of these points.

```
// file: examples/Triangulation_2/terrain.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_euclidean_traits_xy_3<K>   Gt;
typedef CGAL::Delaunay_triangulation_2<Gt>   Delaunay;

typedef K::Point_3   Point;

int main()
{
    std::ifstream in("data/terrain.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;

    Delaunay dt;
    dt.insert(begin, end);
    std::cout << dt.number_of_vertices() << std::endl;
    return 0;
}
```

20.5.3 Example : Voronoi Diagram

The following code computes the edges of Voronoi diagram of a set of data points and counts the number of finite edges and the number of rays of this diagram

```
// file: examples/Triangulation_2/Voronoi.C
```

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Delaunay_triangulation_2<K> Triangulation;
typedef Triangulation::Edge_iterator Edge_iterator;
typedef Triangulation::Point Point;

int main( )
{
    std::ifstream in("data/voronoi.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;
    Triangulation T;
    T.insert(begin, end);

    int ns = 0;
    int nr = 0;
    Edge_iterator eit =T.edges_begin();
    for ( ; eit !=T.edges_end(); ++eit) {
        CGAL::Object o = T.dual(eit);
        K::Segment_2 s;
        K::Ray_2 r;
        if (CGAL::assign(s,o)) {++ns;}
        if (CGAL::assign(r,o)) {++nr;}
    }
    std::cout << "The voronoi diagram as " << ns << "finite edges "
        << " and " << nr << " rays" << std::endl;
    return 0;
}

```

20.6 Regular Triangulations

20.6.1 Description

Let $PW = \{(p_i, w_i), i = 1, \dots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i . Alternatively, each weighted point (p_i, w_i) can be regarded as a sphere (or a circle, depending on the dimensionality of p_i) with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a space partition in which each cell corresponds to a sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere in PW . In the two-dimensional space, the dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i, i = 1, \dots, n\}$ of center points and whose vertices form a subset of P . Such a triangulation is called a regular triangulation. Three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane with equal powers with respect to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) and such that this power is less than the power of p with respect to any other sphere in PW .

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i) , and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) .

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ is a face of the regular triangulation of PW iff the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is positive or null. We call power test of (p_i, w_i) , (p_j, w_j) , (p_k, w_k) , and (p_l, w_l) , the predicates which amount to compute the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i) , (p_j, w_j) and (p_k, w_k) . This predicate amounts to computing the sign of the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_i, w_i) , (p_j, w_j) , (p_k, w_k) , and (p_l, w_l) is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW , is a regular triangulation of PW .

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i), i = 1, \dots, n\}$.

The class *Regular_triangulation_2*<Traits, Tds> is designed to maintain the regular triangulation of a set of 2d weighted points. It derives from the class *Triangulation_2*<Traits, Tds>. The functions *insert* and *remove* are overwritten to handle weighted points and maintain the regular property. The vertices of the regular triangulation of a set of weighted points PW correspond only to a subset of PW . Some of the input weighed points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Such a point is called a hidden point. Because hidden points can reappear later on as vertices when some other point is removed, they have to be stored somewhere. The regular triangulation store those points in special vertices, called hidden vertices. A hidden point can reappear as vertex of the triangulation only when the two dimensional face that hides it is removed from the triangulation. To deal with this feature, each face of a regular triangulation stores a list of hidden vertices. The points in those vertices are reinserted in the triangulation when the face is removed.

Regular triangulation have member functions to construct the vertices and edges of the dual power diagrams.

The geometric traits

The geometric traits of a regular triangulation must provide a weighted point type and a power test on these weighted points. The concept *RegularTriangulationTraits_2*, is a refinement of the concept *TriangulationTraits_2*. CGAL provides the class *Regular_triangulation_euclidean_traits_2*<Rep, Weight> which is a model for the traits concept *RegularTriangulationTraits_2*. The class *Regular_triangulation_euclidean_traits_2*<Rep, Weight> derives from the class *Triangulation_euclidean_traits_2*<Rep> and uses a *Weighted_point* type derived from the type *Point_2* of *Triangulation_euclidean_traits_2*<Rep>.

Note that, since the type *Weighted_point* is not defined in CGAL kernels, plugging a filtered kernel such as *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_2*<K, Weight> will

in fact not provide exact predicates on weighted points. To solve this, there is also another model of the traits concept, *Regular_triangulation_filtered_traits_2<FK>*, which is providing filtered predicates (exact and efficient). The argument *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

The Vertex type and Face Type of a Regular Triangulation

The base vertex type of a regular triangulation includes a boolean to mark the hidden state of the vertex. Therefore CGAL defines the concept *RegularTriangulationVertexBase_2* which refine the concept *TriangulationVertexBase_2* and provides a default model for this concept.

The base face type of a regular triangulation is required to provide a list of hidden vertices, designed to store the points hidden by the face. It has to be a model of the concept *RegularTriangulationFaceBase_2*. CGAL provides the templated class *Regular_triangulation_face_base_2<Traits>* as a default base class for faces of regular triangulations.

20.6.2 Example : a Regular Triangulation

The following code creates a regular triangulation of a set of weighted points and output the number of vertices and the number of hidden vertices.

```
// file: examples/Triangulation_2/regular.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/Regular_triangulation_filtered_traits_2.h>
#include <CGAL/Regular_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Regular_triangulation_filtered_traits_2<K> Traits;
typedef CGAL::Regular_triangulation_2<Traits> Regular_triangulation;

int main()
{
    Regular_triangulation rt;
    std::ifstream in("data/regular.cin");

    Regular_triangulation::Weighted_point wp;
    int count = 0;
    while(in >> wp){
        count++;
        rt.insert(wp);
    }
    rt.is_valid();
    std::cout << "number of inserted points : " << count << std::endl;
    std::cout << "number of vertices : " ;
    std::cout << rt.number_of_vertices() << std::endl;
    std::cout << "number of hidden vertices : " ;
    std::cout << rt.number_of_hidden_vertices() << std::endl;
```

```

    return 0;
}

```

20.7 Constrained Triangulations

A constrained triangulation is a triangulation of a set of points that has to include among its edges a given set of segments joining the points. The corresponding edges are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations.

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges or constrained edges with null length are allowed.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point that is the proper intersection points of two constraints. A single constraint intersecting other constraints will then appear as several edges in the triangulation. The two versions dealing with intersecting constraints differ in the way intersecting constraints are dealt with.
 - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximative.
 - The other one is designed to be used with exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure (which allows one to avoid the cascading of intersection computations) as provided in the class *Constrained_triangulation_plus_2*. See section 20.9.

A constrained triangulation is represented in the CGAL library as an object of the class *Constrained_triangulation_2*<*Traits*,*Tds*,*Itag*>. The third parameter *Itag* is the intersection tag which serves to choose how intersecting constraints are dealt with. This parameter has to be instantiated by one of the following classes : *CGAL::No_intersection_tag* when input constraints do not intersect
CGAL::Exact_predicates_tag if the geometric traits provides exact predicates but approximative constructions
CGAL::Exact_intersections_tag when an exact predicates and exact constructions are provided.

The class *Constrained_triangulation_2*<*Traits*,*Tds*, *Itag*> inherits from *Triangulation_2*<*Traits*,*Tds*>. It defines an additional type *Constraint* to represent the constraints. A constraint is represented as a pair of points.

A constrained triangulation can be created from a list of constrained edges. The class *Constrained_triangulation_2*<*Traits*,*Tds*,*Itag*> overrides the insertion and removal of a point to take care of the information

Figure 20.7: Constrained and Constrained Delaunay triangulation : the constraining edges are the green edges, a constrained triangulation is shown on the left, the constrained Delaunay triangulation with two examples of circumcircles is shown on the right.

about constrained edges. The class also allows inline insertion of a new constraint, given by its two endpoints or the removal of a constraint.

The Geometric Traits

The geometric traits of a constraint triangulation has to be a model of the concept *TriangulationTraits_2*. When intersections of input constraints are supported, the geometric traits class has to be a model of the concept *ConstrainedTriangulationTraits_2* which refines the concept *TriangulationTraits_2* providing additional function object types to compute the intersection of two segments.

The Base Face of a Constrained Triangulation

The information about constrained edges is stored in the faces of the triangulation. The base face of a Constrained Triangulation has to be a model for the concept *ConstrainedTriangulationFaceBase_2* which refines the concept *TriangulationFaceBase_2*. The concept *ConstrainedTriangulationFaceBase_2* requires member functions the get and set the constrained status of the edges.

CGAL provides a default base face class for constrained triangulations. This class, named *ConstrainedTriangulationFaceBase_2<Traits>*, derives from the class *TriangulationFaceBase_2<Traits>* and adds three booleans to store the status of its edges.

20.8 Constrained Delaunay Triangulations

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. As constrained edges are not necessarily Delaunay edges, the triangles of a constrained Delaunay triangulation do not necessarily fulfill the empty circle property but they fulfill a weaker *constrained empty circle property*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay iff the circumscribing circle of any facet encloses no vertex visible from the interior of the facet. As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are provided. The first version handle set of constraints which do not intersect except

possibly at the endpoints. The two other versions handle intersecting input constraints. One of them is designed to be designed to be robust when used in conjunction with a geometric traits providing exact predicates and approximative constructions (such as a *CGAL::Filtered_Kernel* or any kernel providing filtered exact predicates). The third version is designed to be used with an exact arithmetic number type.

The CGAL class *Constrained_Delaunay_triangulation_2*<*Traits,Tds,Itag*> is designed to represent constrained Delaunay triangulations.

As in the case of constraints triangulation, the third parameter *Itag* is the intersection tag and serves to choose how intersecting constraints are dealt with. It can be instantiated with one of the following class : *CGAL::No_intersection_tag*, *CGAL::Exact_predicates_tag*, *CGAL::Exact_intersections_tag* (see Section 20.7).

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2*<*Traits,Tds,Itag*> derives from the class *Constrained_triangulation_2*<*Traits,Tds,Itag*>.

The constrained Delaunay triangulation has member functions to override the insertion and removal of a point or of a constraint. Each of those member function takes care to restore the constrained empty circle property.

The Geometric Traits

The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* predicate as the geometric traits of a Delaunay triangulation and has to a model of the concept *DelaunayTriangulationTraits_2*. When intersecting input constraints are supported the geometric traits is further required to provide function objects to compute constraints intersections. Then the geometric traits has to be at the same time a model of the concept *ConstrainedTriangulationTraits_2*.

The face base class

Information about the status (constrained or not) of the edges of the triangulation has to be stored in the face class and the base face class of a constrained Delaunay triangulation has to be a model of *ConstrainedTriangulationFaceBase_2*.

20.8.1 Example : a constrained Delaunay triangulation

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
// file : examples/Triangulation_2/constrained.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> TDS;
typedef CGAL::Exact_predicates_tag Itag;
```

```

typedef CGAL::Constrained_Delaunay_triangulation_2<K, TDS, Itag> CDT;
typedef CDT::Point Point;

int
main( )
{
    CDT cdt;
    std::cout << "Inserting a grid of 5x5 constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    assert(cdt.is_valid());
    int count = 0;
    for (CDT::Finite_edges_iterator eit = cdt.finite_edges_begin();
        eit != cdt.finite_edges_end();
        ++eit)
        if (cdt.is_constrained(*eit)) ++count;
    std::cout << "The number of resulting constrained edges is ";
    std::cout << count << std::endl;
    return 0;
}

```

20.9 Constrained Triangulations Plus

The class *Constrained_triangulation_plus_2*<Tr> provides a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation. The class *Constrained_triangulation_plus_2*<Tr> inherits from its template parameter Tr, which has to be instantiated by a constrained or constrained Delaunay triangulation. According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection points and refining the input constraints into subconstraints which appear as edges (more precisely as constrained edges) of the triangulation. The data structure maintains for each input constraint the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

The class *Constrained_triangulation_plus_2*<Tr> is especially useful when the base constrained triangulation class handles intersections of constraints and uses an exact number type, i.e. when its intersection tag is *CGAL::Exact_intersections_tag*. Indeed in this case, the *Constrained_triangulation_plus_2*<Tr> is specially designed to avoid cascading in the computations of intersection points.

20.9.1 Example : Building a triangulated arrangement of segments

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
// file: examples/Triangulation_2/constrained_plus.C
```

```

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

struct K : CGAL::Exact_predicates_exact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K>          Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>   TDS;
typedef CGAL::Exact_intersections_tag                 Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Constrained_triangulation_plus_2<CDT>    CDTplus;
typedef CDTplus::Point                                 Point;

int
main( )
{
    CDTplus cdt;
    std::cout << "Inserting a grid 5 x 5 of constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    assert(cdt.is_valid());
    int count = 0;
    for (CDTplus::Subconstraint_iterator scit = cdt.subconstraints_begin();
         scit != cdt.subconstraints_end();
         ++scit) ++count;
    std::cout << "The number of resulting constrained edges is  "
              << count << std::endl;
    return 0;
}

```

20.10 The Triangulation Hierarchy

The class *Triangulation_hierarchy_2<Tr>* implements a triangulation augmented with a data structure to answer efficiently point location queries. The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceeding level. Point location is done through a top down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceeding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceeding triangulation, the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behaviour when it is built for Delaunay triangulations. However it can be used as well for other triangulations and the class *Triangulation_hierarchy_2<Tr>* is templated by a parameter which is to be instantiated by one of the CGAL triangulation classes.

The class *Triangulation_hierarchy_2<Tr>* inherits from the triangulation type passed as template parameter *Tr*.

The insert and remove member functions are overwritten to update the data structure at each operation. The locate queries are also overwritten to take advantage of the data structure for a fast processing.

The Vertex of a Triangulation Hierarchy

The base vertex class of a triangulation hierarchy has to be a model of the concept *TriangulationHierarchyVertexBase_2* which extends the concept *TriangulationVertexBase_2*. This extension adds access and setting member functions for two pointers to the corresponding vertices in the triangulations of the next and preceeding levels.

CGAL provides the class *Triangulation_hierarchy_vertex_base_2<Vb>* which is a model for the concept *TriangulationHierarchyVertexBase_2*. This class is templated by a parameter *Vb* which is to be instantiated by a model of the concept *TriangulationVertexBase_2*. The class *Triangulation_hierarchy_vertex_base_2<Vb>* inherits from its template parameter *Vb*. This design allows to use for *Vb* either the default vertex class or a user customized vertex class with additional functionalities.

20.10.1 Examples of the Use of a Triangulation Hierarchy

The following program is example of the standard use of a triangulation hierarchy to enhance the efficiency of a Delaunay triangulation. The program output the number of vertices at the different levels of the hierarchy.

```
// file: examples/Triangulation_2/hierarchy.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>
#include <cassert>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K> Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Triangulation_hierarchy_2<Dt> Triangulation;
typedef Triangulation::Point Point;
typedef CGAL::Creator_uniform_2<double,Point> Creator;

int main( )
{
    std::cout << "insertion of 1000 random points" << std::endl;
    Triangulation t;
    CGAL::Random_points_in_square_2<Point,Creator> g(1.);
    CGAL::copy_n( g, 1000, std::back_inserter(t));

    //verbose mode of is_valid ; shows the number of vertices at each level
    std::cout << "The number of vertices at successive levels" << std::endl;
```

```

    assert(t.is_valid(true));

    return 0;
}

```

The following program shows how to use a triangulation hierarchy in conjunction with a constrained triangulation plus.

```

// file: examples/Triangulation_2/constrained_hierarchy_plus.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K>          Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>    TDS;
typedef CGAL::Exact_predicates_tag                      Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Triangulation_hierarchy_2<CDT>           CDTH;
typedef CGAL::Constrained_triangulation_plus_2<CDTH>    Triangulation;

typedef Triangulation::Point                            Point;

int
main( )
{
    Triangulation cdt;
    std::cout << "Inserting a grid 5 x 5 of constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    int count = 0;
    for (Triangulation::Subconstraint_iterator scit = cdt.subconstraints_begin();
         scit != cdt.subconstraints_end();
         ++scit) ++count;
    std::cout << "The number of resulting constrained edges is ";
    std::cout << count << std::endl;

    //verbose mode of is_valid ; shows the number of vertices at each level
    std::cout << "The number of vertices at successive levels" << std::endl;
    assert(cdt.is_valid(true));

    return 0;
}

```

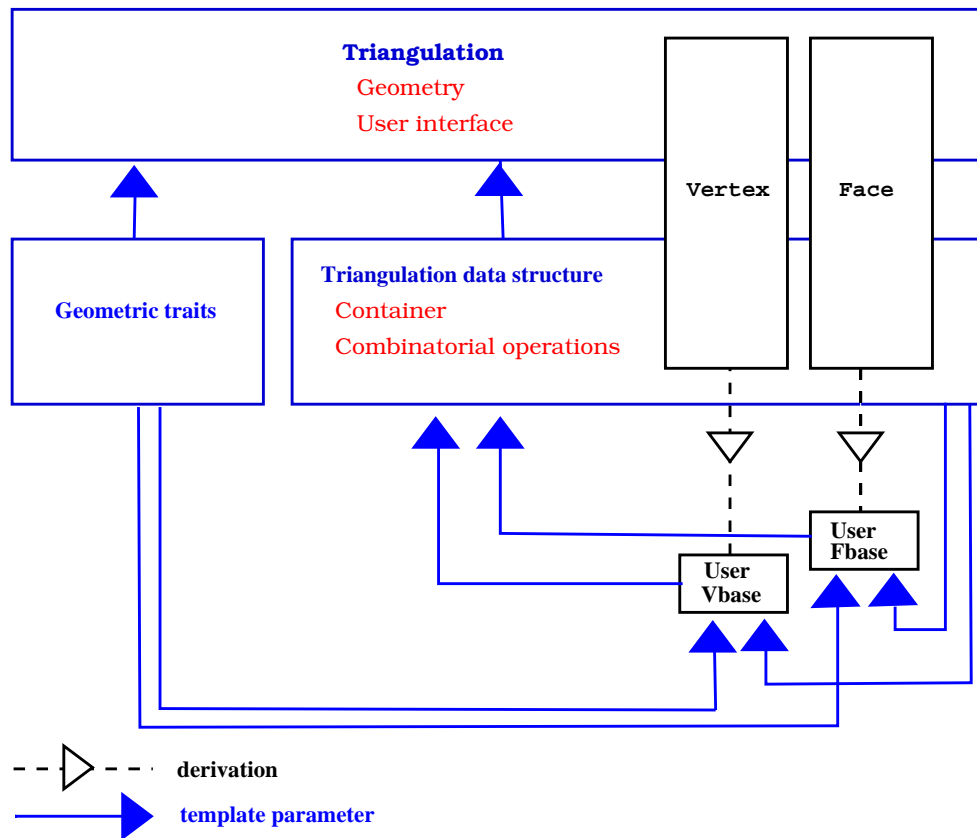

Figure 20.8: The cyclic dependency in triangulations software design.

20.11 Flexibility: Using Customized Vertices and Faces

To be able to adapt to various needs, a highly flexible design has been selected for 2D triangulations. We have already seen that the triangulation classes have two parameters : a geometric traits class and a triangulation data structure class which the user can instantiate with his own customized classes.

The most useful flexibility however comes from the fact that the triangulation data structure itself has two template parameters to be instantiated by classes for the vertices and faces of the triangulation. Using his own customized classes to instantiate these parameters, the user can easily build up a triangulation with additional information or functionality in the vertices and faces.

A cyclic dependency

To insure flexibility, the triangulation data structure is templated by the vertex and face base classes. Also since incidence and adjacency relations are stored in vertices and faces, the base classes have to know the types of handles on vertices and faces provided by the triangulation data structure. Thus the vertex and base classes have to be themselves parameterized by the triangulation data structure, and there is a cyclic dependency on template parameter.

Previously, this cyclic dependency was avoided by using only *void** pointers in the interface of base classes. These *void** were converted to appropriate types at the triangulation data structure levels. This solution had

some drawbacks : mainly the user could not add in the vertices or faces of the triangulation a functionality related to types defined by the triangulation data structure, for instance a handle to a vertex, and he was lead to use himself *void** pointers). The new solution to resolve the template dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class `std::allocator`. The rebind mechanism is described in Section 21.3 of Chapter 21. For now, we will just notice that the design requires the existence in the vertex and face base classes of a nested template class *Rebind_TDS* defining a type *Other* used by the rebinding mechanism.

The two following examples show how the user can put in use the flexibility offered by the base classes parameters.

Adding colors

The first example corresponds to a case where the user wishes to add in the vertices or faces of the triangulation an additional information that does not depend on types provided by the triangulation data structure. In that case, predefined classes *Triangulation_vertex_base_with_info_2*<*Info*,*Traits*,*Vb*> or *Triangulation_face_base_with_info_2*<*Info*,*Traits*,*Vb*> can be used. Those classes have a template parameter *Info* devoted to handle additional information. The following examples shows how to add a *CGAL::Color* in the triangulation faces.

```
// file : examples/Triangulation_2/colored_face.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Triangulation_2.h>
#include <CGAL/Triangulation_face_base_with_info_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Triangulation_face_base_with_info_2<CGAL::Color,K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Face_handle Face_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point Point;

int main() {
    Triangulation t;
    t.insert(Point(0,1));
    t.insert(Point(0,0));
    t.insert(Point(2,0));
    t.insert(Point(2,2));

    Finite_faces_iterator fc = t.finite_faces_begin();
    for( ; fc != t.finite_faces_end(); ++fc) fc->info() = CGAL::BLUE;

    Point p(0.5,0.5);
    Face_handle fh = t.locate(p);
    fh->info() = CGAL::RED;

    return 0;
}
```

```
}
```

Adding handles

The second example shows how the user can still derive and plug in his own vertex or face class when he would like to have additional functionalities depending on types provided by the triangulation data structure.

```
// file : examples/Triangulation_2/adding_handles.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>
#include <cassert>

/* A facet with an additionnal handle */
template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt> >
class My_vertex_base
: public Vb
{
    typedef Vb                                Base;
public:
    typedef typename Vb::Vertex_handle        Vertex_handle;
    typedef typename Vb::Face_handle          Face_handle;
    typedef typename Vb::Point                Point;

    template < typename TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<Gt,Vb2>                            Other;
    };

private:
    Vertex_handle va_;

public:
    My_vertex_base() : Base() {}
    My_vertex_base(const Point & p) : Base(p) {}
    My_vertex_base(const Point & p, Face_handle f) : Base(f,p) {}
    My_vertex_base(Face_handle f) : Base(f) {}

    void set_associated_vertex(Vertex_handle va) { va_ = va;}
    Vertex_handle get_associated_vertex() {return va_ ; }
};

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef My_vertex_base<K> Vb;
typedef CGAL::Triangulation_data_structure_2<Vb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point Point;
```

```

int main() {
    Triangulation t;
    Vertex_handle v0 = t.insert(Point(0,1));
    Vertex_handle v1 = t.insert(Point(0,0));
    Vertex_handle v2 = t.insert(Point(2,0));
    Vertex_handle v3 = t.insert(Point(2,2));

    // associate vertices as you like
    v0->set_associated_vertex(v1);
    v1->set_associated_vertex(v2);
    v2->set_associated_vertex(v3);
    v3->set_associated_vertex(v0);
    assert( v0->get_associated_vertex() == v1);

    return 0;
}

```

20.12 Design and Implementation History

The code of this package is the result of a long development process. Here follows a tentative list of people who added their stone to this package : Jean-Daniel Boissonnat, Hervé Brönnimann, Olivier Devillers, Andreas Fabri, Frédéric Fichel, Julia Flötotto, Monique Teillaud and Mariette Yvinec.

2D Triangulations

Reference Manual

Mariette Yvinec

A triangulation is a 2-dimensional simplicial complex which is pure connected and without singularities. Thus a triangulation can be viewed as a collection of triangular faces, such that two faces either have an empty intersection or share an edge or a vertex.

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces. The edges are not explicitly represented, they are only represented through the adjacencies relations of two faces.

The triangulation classes of CGAL depend on two template parameters. The first template parameter stands for a geometric traits class which is assumed to provide the geometric objects (points, segments and triangles) forming the triangulation and the geometric predicates on those objects. The second template parameter stands for a model of triangulation data structure acting as a container for faces and vertices while taking care of the combinatorial aspects of the triangulation. The concepts and models relative to the triangulation data structure are described in Chapter 21.

ConstrainedDelaunayTriangulationTraits_2

Definition

The concept `ConstrainedDelaunayTriangulationTraits_2` defines the requirements for the geometric traits class of a constrained Delaunay triangulation that supports intersections of input constraints. This is the case when the template parameter *Itag* of (*Constrained_Delaunay_triangulation_2*<*Traits*,*Tds*,*Itag*>) is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*. The concept `ConstrainedDelaunayTriangulationTraits_2` refines both the concept *DelaunayTriangulationTraits_2* and the concept *ConstrainedTriangulationTraits_2*.

ConstrainedTriangulationFaceBase_2

Definition

In a constrained triangulation, the information about constrained edges is stored in the faces of the triangulation. The base face of a constrained triangulation has to be a model of the concept `ConstrainedTriangulationFaceBase_2` which refines the concept `TriangulationFaceBase_2` providing functionalities to deal with constraints.

Refines

`TriangulationFaceBase_2`

Types

Defines the same types as the `TriangulationFaceBase_2` concept

Access Functions

`bool f.is_constrained(int i)`

returns true if the edge between f and its neighbor $f.\text{neighbor}(i)$ is constrained.
Precondition: $0 \leq i \leq 2$.

— advanced —

Modifiers

`void f.set_constraint(int i, bool b)`

sets the edge between f and its neighbor $f.\text{neighbor}(i)$ as a constrained or unconstrained edge according to b .

`void f.set_constraints(bool c0, bool c1, bool c2)`

sets the status (constrained or unconstrained) of the three edges of f .

`void f.reorient()`

Changes the orientation of f by exchanging $\text{vertex}(0)$ with $\text{vertex}(1)$ and $\text{neighbor}(0)$ with $\text{neighbor}(1)$ and the corresponding constrained status.

`void f.ccw_permute()`

performs a counterclockwise permutation of the vertices, neighbors and constrained status of f .

`void f.cw_permute()`

performs a clockwise permutation of the vertices and neighbors and constrained status of f .

Miscellaneous

bool *f.is_valid()* tests the validity of face *f* as a face of a plain triangulation and additionally checks if the edges of *f* are consistently marked as constrained or unconstrained edges in face *f* and its neighbors.

ConstrainedTriangulationTraits_2

Definition

The concept `ConstrainedTriangulationTraits_2` defines the requirements for the geometric traits class of a constrained triangulation (*Constrained_Triangulation_2*<*Traits*,*Tds*,*Itag*>) that supports intersections of input constraints (i. e. when the template parameter *Itag* is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*). This concept refines the concept *TriangulationTraits_2*, adding requirements for function objects to compute the intersection points of two constraints. When *Exact_predicates_tag* is used, the traits class is also required to provide additional types to compute the squared distance between a point and a line

Refines

TriangulationTraits_2

Types

ConstrainedTriangulationTraits_2:: Intersect_2

A function object whose operator() computes the intersection of two segments :

Object_2 operator()(Segment_2 s1, Segment_2 s2); Returns the intersection of *s1* and *s2*.

When the constrained triangulation is instantiated with the intersection tag *Exact_predicates_tag*, the used algorithms needs to be able to compare some distances between points and lines and the following types are further required.

ConstrainedTriangulationTraits_2:: RT

A number type supporting the comparison operator <.

ConstrainedTriangulationTraits_2:: Line_2

The line type.

ConstrainedTriangulationTraits_2:: Construct_line_2

A function object whose operator() constructs a line from two points :

Line_2 operator()(Point_2 p1, Point_2 p2);

ConstrainedTriangulationTraits_2:: Compute_squared_distance_2

A function object with an operator() designed to compute the squared distance between a line and a point : *RT operator()(Point_2 p1, Line_2);* Return the squared distance between *p* and *l*.

Access to constructor object

Intersect_2

traits.intersect_2_object()

Construct_line_2 *traits.construct_line_2_object()*

required when the intersection tag is *Exact_predicates_tag*.

Compute_squared_distance_2

traits.compute_squared_distance_2_object()

required when the intersection tag is *Exact_predicates_tag*.

CGAL::Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>

Definition

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. Constrained edges are not necessarily Delaunay edges, therefore a constrained Delaunay triangulation is not a Delaunay triangulation. A constrained Delaunay is a triangulation whose faces do not necessarily fulfill the empty circle property but fulfill a weaker property called the *constrained empty circle*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay if the circumscribing circle of any of its triangular faces includes in its interior no vertex that is visible from the interior of the triangle. The class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* is designed to represent constrained Delaunay triangulations.

As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are offered depending on whether the user wishes to handle intersecting input constraints or not. The desired version can be selected through the instantiation of the third template parameter *Itag* which can be one of the following : *CGAL::No_intersection_tag* if intersections of input constraints are disallowed, *CGAL::Exact_predicates_tag* allows intersections between input constraints and is to be used when the traits class provides exact predicates but approximate constructions of the intersection points. *CGAL::Exact_intersections_tag* allows intersections between input constraints and is to be used in conjunction with an exact arithmetic type.

The template parameters *Tds* has to be instantiate with a model of *TriangulationDataStructure_2*. The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* test as the geometric traits of a Delaunay triangulation and the *Traits* parameter has to be instantiated with a model *DelaunayTriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. and has then to be also a model of the concept *ConstrainedTriangulationTraits_2*.

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* derives from the class *Constrained_triangulation_2<Traits,Tds>*. Also, information about the status (constrained or not) of the edges of the triangulation is stored in the faces. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides a default for the template parameters. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2<CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt>>*. The default intersection tag is *CGAL::No_intersection_tag*.

```
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
```

Inherits From

Constrained_triangulation_2<Traits,Tds,Itag>

Types

All types used in this class are inherited from the base class *Constrained_triangulation_2**<Traits,Tds,Itag>*.

Creation

`Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt(Traits t = Traits());`

Introduces an empty constrained Delaunay triangulation *cdt*.

$$\text{Constrained_Delaunay_triangulation_2} \langle \text{Traits}, \text{Tds}, \text{Itag} \rangle \text{ cdt}(\text{Constrained_Delaunay_triangulation_2 cdt1});$$

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

$$\text{Constrained_Delaunay_triangulation_2}\langle \text{Traits}, \text{Tds}, \text{Itag} \rangle \text{ cdt}(\text{list}\langle \text{Constrained} \rangle \& \text{lc}, \text{Traits } t = \text{Traits}());$$

Introduces a constrained triangulation, the constrained edges of which are the edges of the list lc .

[illegible]

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range $[first, last)$.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

Insertion and Removal

The following member functions overwrite the corresponding members of the base class to include a step restoring the Delaunay constrained property after modification of the triangulation.

```
Vertex_handle      cdt.insert( Point p, Face_handle f = Face_handle())
```

Inserts point p in the triangulation. If present f is used as an hint for the location of p .

<i>Vertex_handle</i>	<i>cdt.insert(Point p, Locate_type& lt, Face_handle loc, int li)</i>
----------------------	---------------------------------------------------------------------------

Same as above except that the location of the point p to be inserted is assumed to be given by (lt, loc, i) .

Vertex_handle cdt.push_back(Point p)

Equivalent to $insert(p)$.

template < class InputIterator >

int *cdt.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *cdt.insert_constraint(Point a, Point b)*

Inserts segment *ab* as a constrained edge in the triangulation.

void *cdt.push_back(Constraint c)*

Inserts constraints *c* as above.

void *cdt.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts the line segment whose endpoints are the vertices *va* and *vb* as a constrained edge *e* in the triangulation.

void *cdt.remove(Vertex_handle & v)*

Removes vertex *v*.

Precondition: Vertex *v* is not incident to a constrained edge.

void *cdt.remove_incident_constraints(Vertex_handle v)*

Make the edges incident to vertex *v* unconstrained edges.

void *cdt.remove_constraint(Face_handle f, int i)*

Edge (f,i) is no longer constrained.

Queries

The following template member functions query the set of faces in conflict with a point *p*. The notion of conflict refers here to a constrained Delaunay setting which means the following. Constrained edges are considered as visibility obstacles and a point *p* is considered to be in conflict with a face *f* iff it is visible from the interior of *f* and included in the circumcircle of *f*.

template <class OutputItFaces, class OutputItBoundaryEdges>

std::pair<OutputItFaces,OutputItBoundaryEdges>

cdt.get_conflicts_and_boundary(Point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,

Face_handle start)

OutItFaces is an output iterator with *Face_handle* as value type. *OutItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are ouput in counterclockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a `std::pair` the resulting output iterators.

```
template <class OutputItFaces>
OutputItFaces      cdt.get_conflicts( Point p, OutputItFaces fit, Face_handle start)
```

Same as above except that only the faces in conflict with *p* are output. The function returns the resulting output iterator.

```
template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

      cdt.get_boundary_of_conflicts( Point p,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This functions outputs in the container pointed to by *eit*, the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are ouput in counterclockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns the resulting output iterator.

Checking

<i>bool</i>	<i>cdt.is_valid()</i>	Checks if the triangulation is valid and if each constrained edge is consistently marked constrained in its two incident faces.
-------------	-----------------------	---------------------------------------------------------------------------------------------------------------------------------

└────────── advanced ─────────┘

Flips

<i>bool</i>	<i>cdt.is_flipable(Face_handle f, int i)</i>	Determines if edge (f,i) can be flipped. Returns true if edge (f,i) is not constrained and the circle circumscribing <i>f</i> contains the vertex of $f->neighbor(i)$ opposite to edge (f,i) .
-------------	-----------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

void *cdt.flip(Face_handle& f, int i)*

Flip *f* and *f->neighbor(i)*.

void *cdt.propagating_flip(List_edges & edges)*

Makes the triangulation constrained Delaunay by flipping edges. List edges contains an initial list of edges to be flipped. The returned triangulation is constrained Delaunay if the initial list contains at least all the edges of the input triangulation that failed to be constrained Delaunay. (An edge is said to be constrained Delaunay if it is either constrained or locally Delaunay.)

CGAL::Constrained_triangulation_2<Traits,Tds,Itag>

Definition

A constrained triangulation is a triangulation of a set of points which has to include among its edges a given set of segments joining the points. The given segments are called *constraints* and the corresponding edges in the triangulation are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges are allowed as well as constrained edges with null length.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point which is a proper intersection point of two constraints. A single constraint intersecting other constraints will then appear as the union of several constrained edges of the triangulation. The two versions dealing with intersecting constraints, slightly differ in the way intersecting constraints are dealt with.
 - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximative.
 - The other one is designed to be used with an exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure as provided in the class *Constrained_triangulation_plus_2*. See section 20.9.

The class *Constrained_triangulation_2<Traits,Tds,Itag>* of the CGAL library implements constrained triangulations. The template parameter *Traits* stands for a geometric traits class. It has to be a model of the concept *TriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. It has then to be a model of the concept *ConstrainedTriangulationTraits_2*. The template parameter *Tds* stands for a triangulation data structure class that has to be a model of the concept *TriangulationDataStructure_2*. The third parameter *Itag* is the intersection tag which serves to choose between the different strategies to deal with constraints intersections. CGAL provides three valid types for this parameter :

CGAL::No_intersection_tag disallows intersections of input constraints,

CGAL::Exact_predicates_tag is to be used when the traits class provides exact predicates but approximate constructions of the intersection points.

CGAL::Exact_intersections_tag is to be used in conjunction with an exact arithmetic type.

The information about constrained edges is stored in the faces of the triangulation. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional

functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides default instantiations for the template parameters *Tds* and *Itag*, and for the *ConstrainedTriangulationFaceBase_2*. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2 <CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

Introduces a constrained triangulation, the constrained edges of which are the edges of the list *lc*.

```
template<class InputIterator>
```

```
Constrained_triangulation_2<Traits,Tds,Itag> ct( InputIterator first, InputIterator last, Traits t=Traits());
```

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range *[first, last)*.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

Queries

bool *ct.is_constrained(Edge e)*

Returns true if edge *e* is a constrained edge.

bool *ct.are_there_incident_constraints(Vertex_handle v)*

Returns true if at least one of the edges incident to vertex *v* is constrained.

template<class OutputItEdges>

OutputItEdges *ct.incident_constraints(Vertex_handle v, OutputItEdges out)*

OutputItEdges is an output iterator with *Edge* as value type. Outputs the constrained edges incident to *v* in the sequence pointed to by *out* and returns the resulting output iterator.

Insertion and removal

Vertex_handle *ct.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* and restores the status (constrained or not) of all the touched edges. If present *f* is used as an hint for the location of *p*.

Vertex_handle *ct.insert(Point p, Locate_type& lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by *(lt,loc,i)*.

Vertex_handle *ct.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >

int *ct.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *ct.insert_constraint(Point a, Point b)*

Inserts points *a* and *b*, and inserts segment *ab* as a constraint. Removes the faces crossed by segment *ab* and creates new faces instead. If a vertex *c* lies on segment *ab*, constraint *ab* is replaced by the two constraints *ac* and *cb*. Apart from the insertion of *a* and *b*, the algorithm runs in time proportionnal to the number of removed triangles.

Precondition: The relative interior of segment *ab* does not intersect the relative interior of another constrained edge.

void *ct.push_back(Constraint c)*

Inserts constraints *c* as above.

void *ct.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts the line segment *s* whose endpoints are the vertices *va* and *vb* as a constrained edge *e*. The triangles intersected by *s* are removed and new ones are created.

void *ct.remove(Vertex_handle v)*

Removes a vertex *v*.

Precondition: Vertex *v* is not incident to a constrained edge.

void *ct.remove_incident_constraints(Vertex_handle v)*

Make the edges incident to vertex *v* unconstrained edges.

void *ct.remove_constrained_edge(Face_handle f, int i)*

Make edge *(f,i)* no longer constrained.

┌────────── *advanced* ───────────┐
|
bool *ct.is_valid(bool verbose = false, int level = 0)*

Checks the validity of the triangulation and the consistency of the constrained marks in edges.

└────────── *advanced* ───────────┘

I/O

ostream & *ostream& os << Constrained_triangulation_2<Traits,Tds> Ct*

Writes the triangulation and, for each face *f*, and integers *i=0,1,2*, write “C” or “N” depending whether edge *(f,i)* is constrained or not.

Implementation

The insertion of a constrained edge runs in time proportionnal to the number of triangles intersected by this edge.

CGAL::Constrained_triangulation_face_base_2<Traits,Fb>

Definition

The class *Constrained_triangulation_face_base_2<Traits,Fb>* is the default model for the concept *ConstrainedTriangulationFaceBase_2* to be used as base face class of constrained triangulations.

```
#include <CGAL/Constrained_triangulation_face_base_2.h>
```

Is Model for the Concepts

ConstrainedTriangulationFaceBase_2

Parameters

The first template parameter is a geometric traits.

The second template parameter has to be a model of the concept *TriangulationFaceBase_2*. Its default is *CGAL::Triangulation_face_base_2<Traits>*

Inherits From

The class *Constrained_triangulation_face_base_2<Traits,Fb>* derives from its parameter *Fb*. and add three boolean to deal with information about constrained edges.

The member functions *cw(int i)*, *ccw(int i)* and *reorient* are overloaded to update information about constrained edges.

CGAL::Triangulation_face_base_2<Traits>

CGAL::Constrained_triangulation_plus_2<Tr>

The class *Constrained_triangulation_plus_2<Tr>* implements a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation.

The class *Constrained_triangulation_plus_2<Tr>* inherits from its template parameter *Tr*, which has to be instantiated by a constrained or constrained Delaunay triangulation.

According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection point and refining the input constraints into subconstraints which are edges (more precisely constrained edges) of the triangulation. In this context, the constraint hierarchy keeps track of the input constraints and of their refinement in the triangulation. This data structure maintains for each input constraints the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

```
#include <CGAL/Constrained_triangulation_plus_2.h>
```

Inherits From

Tr

Types

<i>typedef Tr</i>	<i>Triangulation;</i>	the triangulation base class.
<i>typedef Itag</i>	<i>Intersection_tag;</i>	the intersection tag.s

```
Constrained_triangulation_plus_2<Tr>:: Constraint_iterator;
```

An iterator to visit all the input constraints. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the endpoints of the constraint.

```
Constrained_triangulation_plus_2<Tr>:: Subconstraint_iterator;
```

An iterator to visit all the subconstraints of the triangulation. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the vertices of the subconstraint.

```
Constrained_triangulation_plus_2<Tr>:: Vertices_in_constraint_iterator;
```

An iterator on the vertices of the chain of triangulation edges representing a constraint. The value type of this iterator is *Vertex_handle*.

<i>typedef</i>	<i>Context</i> ;	This type is intended to describe a constraint enclosing a sub-constraint and the position of the subconstraint in this constraint. It provides three member functions <i>vertices_begin()</i> , <i>vertices_end()</i> and <i>current()</i> returning iterators of the type <i>Vertices_in_constraint_iterator</i> on the sequence of vertices of the enclosing constraint. These iterators point respectively on the first vertex of the enclosing constraint, past the last vertex and on the first vertex of the subconstraint.
<i>typedef</i>	<i>Context_iterator</i> ;	An iterator on constraints enclosing a given subconstraint. The value type of this iterator is <i>Context</i> .

Creation

Constrained_triangulation_plus_2<Tr> *ctp*(*Geom_traits* gt=*Geom_traits*());

Introduces an empty triangulation.

Constrained_triangulation_plus_2<Tr> *ctp*(*Constrained_triangulation_plus_2* ct);

Copy constructor.

Constrained_triangulation_plus_2<Tr> *ctp*(*std::list*<*Constrained*>& lc, *Geom_traits* t = *Geom_traits*());

Introduces and builds a constrained triangulation from the list of constraints *lc*.

template<*class InputIterator*>
Constrained_triangulation_plus_2<Tr> *ctp*(*InputIterator* first,
InputIterator last,
Geom_traits gt= *Geom_traits*())

Introduces and builds a constrained triangulation from the constraints in the range *[first, last)*.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

void *~ctp*()

Destructor. All vertices and faces are deleted. The constraint hierarchy is deleted.

Assignment

Constrained_triangulation_plus_2

ctp = *Constrained_triangulation_plus_2* tr

Assignment. All the vertices and faces are duplicated. The constraint hierarchy is also duplicated.

void *ctp.swap(Constrained_triangulation_plus_2 tr)*

The triangulations *tr* and *ctp* are swapped. This operation should be preferred to *ctp = tr* or to *t(tr)* if *tr* is deleted after that.

Insertion and Removal

The class *Constrained_triangulation_plus_2<Tr>* overwrites the following insertion and removal member functions for points and constraints.

Vertex_handle *ctp.insert(Point p, Face_handle start = Face_handle())*

Inserts point *p* as a vertex of the triangulation.

Vertex_handle *ctp.insert(Point p, Locate_type lt, Face_handle loc, int li)*

inserts a point *p* whose location is assumed to be given by *(lt,loc,li)*.

Vertex_handle *ctp.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >

int *ctp.insert(InputIterator first, InputIterator last)*

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *ctp.insert_constraint(Point a, Point b)*

Inserts the constraint segment *ab* in the triangulation.

void *ctp.push_back(Constraint c)*

Inserts the constraint *c*.

void *ctp.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts a constraint whose endpoints are the vertices pointed by *va* and *vb* in the triangulation.

<i>void</i>	<i>ctp.remove_constraint(Vertex_handle va, Vertex_handle vb)</i>	<p>Removes the constraint joining the vertices pointed by <i>va</i> and <i>vb</i>.</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> have to refer to the endpoint vertices of an input constraint.</p>
Queries		
<i>Constraint_iterator</i>	<i>ctp.constraints_begin()</i>	Returns a <i>Constraint_iterator</i> pointing on the first constraint.
<i>Constraint_iterator</i>	<i>ctp.constraints_end()</i>	Returns a <i>Constraint_iterator</i> pointing past the last constraint.
<i>Subconstraint_iterator</i>	<i>ctp.subconstraints_begin()</i>	Returns a <i>Subconstraint_iterator</i> pointing on the first subconstraint.
<i>Subconstraint_iterator</i>	<i>ctp.subconstraints_end()</i>	Returns a <i>Subconstraint_iterator</i> pointing past the last subconstraint.
<i>int</i>	<i>ctp.number_of_enclosing_constraints(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns the number of constraints enclosing the subconstraint (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context</i>	<i>ctp.context(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns the <i>Context</i> relative to one of the constraint enclosing the subconstraint (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context_iterator</i>	<i>ctp.contexts_begin(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns an iterator pointing on the first <i>Context</i> of the sequence of <i>Contexts</i> corresponding to the constraints enclosing the subconstraint(<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context_iterator</i>	<i>ctp.contexts_end(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns an iterator past the last <i>Context</i> of the sequence of <i>Contexts</i> corresponding to the constraints enclosing the (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_begin(Vertex_handle va, Vertex_handle vb)

Returns an iterator on the first vertex on the constraint (*va,vb*)

Precondition: *va* and *vb* refer to the vertices of an input constraint.

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_end(Vertex_handle va, Vertex_handle vb)

Returns an iterator past the last vertex on the constraint (*va,vb*)

Precondition: *va* and *vb* refer to the vertices of an input constraints.

ConstrainedTriangulationTraits_2

ConstrainedDelaunayTriangulationTraits_2

DelaunayTriangulationTraits_2

Definition

In addition to the requirements of the concept *TriangulationTraits_2* described page 1424, the concept *DelaunayTriangulationTraits_2* provide a predicate to check the empty circle property. The corresponding predicate type is called type *Side_of_oriented_circle_2*.

The additional types *Line_2*, *Ray_2* and the constructor objects *Construct_ray_2* *Construct_circumcenter_2*, *Construct_bisector_2*, *Construct_midpoint* are used to build the dual Voronoi diagram and are required only if the dual functions are called. The additional predicate type *Compare_distance_2* is required if calls to *nearest_vertex(..)* are issued.

Refines

TriangulationTraits_2

Types

DelaunayTriangulationTraits_2:: Line_2 The line type. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Ray_2 The type for ray. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Side_of_oriented_circle_2

Predicate type. Provides the operator :
Oriented_side operator()(Point p, Point q, Point r, Point s) which takes four points *p,q,r,s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or *ON_ORIENTED_BOUNDARY* according to the position of points *s* with respect to the oriented circle through *p,q* and *r*.

DelaunayTriangulationTraits_2:: Compare_distance_2

Predicate type. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q, Point_2 r) which returns *SMALLER*, *EQUAL* or *LARGER* according to the distance between *p* and *q* being smaller, equal or larger than the distance between *p* and *r*. This type is only require if *nearest_vertex* queries are issued.

DelaunayTriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point_2 operator()(Point_2 p, Point_2 q, Point_2 r) which returns the circumcenter of the three points *p, q* and *r*. This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_bisector_2

Constructor object. Provides the operator :
Line_2 operator()(Point_2 p, Point_2 q) which constructs the bisector line of points p and q . This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_ray_2

A constructor object to build a ray from a point and a line.
Provides :
Ray_2 operator() (Point_2 p, Line_2 l);

Creation

DelaunayTriangulationTraits_2 traits; default constructor.
DelaunayTriangulationTraits_2 traits(dt); copy constructor
DelaunayTriangulationTraits_2 traits = traits2

Assignment operator.

Access to predicate and constructor objects

Side_of_oriented_circle_2 traits.side_of_oriented_circle_2_object()

The following functions are required only if member functions of the Delaunay triangulation relative to the dual Voronoi diagram are called. *Compare_distance_2 traits.compare_distance_2_object()*

Construct_circumcenter_2 traits.construct_circumcenter_2_object()

Construct_bisector_2 traits.construct_bisector_2_object()

Construct_direction_2 traits.construct_direction_2_object()

Construct_ray_2 traits.construct_ray_2_object()

CGAL::Triangulation_euclidean_traits_zx_3<Rep>.

See Also

TriangulationTraits_2

CGAL::Delaunay_triangulation_2<Traits,Tds>

Definition

The class *Delaunay_triangulation_2<Traits,Tds>* is designed to represent the Delaunay triangulation of a set of points in a plane. A Delaunay triangulation of a set of points is a triangulation of the sets of points that fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no point of the set in its interior. For a point set with no case of cocircularity of more than three points, the Delaunay triangulation is unique, it is the dual of the Voronoi diagram of the points.

Inherits From

Triangulation_2<Traits,Tds>.

Parameters

The template parameter *Tds* is to be instantiated with a model of *TriangulationDataStructure_2*. CGAL provides a default instantiation for this parameter, which is the class *CGAL::Triangulation_data_structure_2 <CGAL::Triangulation_vertex_base_2<Traits>, CGAL::Triangulation_face_base_2<Traits> >*.

The geometric traits *Traits* is to be instantiated with a model of *DelaunayTriangulationTraits_2*. The concept *DelaunayTriangulationTraits_2* refines the concept *TriangulationTraits_2*, providing a predicate type to check the empty circle property.

Changing this predicate type allows to build Delaunay triangulations for different metrics such that L_1 or L_∞ or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points. The concept of *DelaunayTriangulationTraits_2* is described page [1399](#).

When dealing with a large triangulations, the user is advised to encapsulate the Delaunay triangulation class into a triangulation hierarchy, which means to use the class *Triangulation_hierarchy_2<Tr>* with the template parameter instantiated with *Delaunay_triangulation_2<Traits,Tds>*. The triangulation hierarchy will then offer the same functionalities but be much more efficient for locations and insertions.

```
#include <CGAL/Delaunay_triangulation_2.h>
```

Inherits From

Triangulation_2<Traits,Tds>

Types

Inherits all the types defined in *Triangulation_2<Traits,Tds>*.

Creation

Delaunay_triangulation_2<Traits,Tds> dt(Traits gt = Traits());

default constructor.

Delaunay_triangulation_2<Traits,Tds> dt(tr);

copy constructor. All the vertices and faces are duplicated.

Insertion and Removal

The following insertion and removal functions overwrite the functions inherited from the class *Triangulation_2*<Traits,Tds> to maintain the Delaunay property.

Vertex_handle dt.insert(Point p, Face_handle f=Face_handle())

inserts point *p*. If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation is not updated. Optional parameter *f* is used to initialize the location of *p*.

Vertex_handle dt.insert(Point p, Locate_type& lt, Face_handle loc, int li)

inserts a point *p*, the location of which is supposed to be given by (*lt,loc,li*), see the description of member function *locate* in class *Triangulation_2*<Traits,Tds>.

Vertex_handle dt.push_back(Point p)

equivalent to *insert(p)*.

template < class InputIterator >

int dt.insert(InputIterator first, InputIterator last)

inserts the points in the range [*first, last*). Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void dt.remove(Vertex_handle v)

removes the vertex from the triangulation.

Note that the other modifier functions of *Triangulation_2*<Traits,Tds> are not overwritten. Thus a call to *insert_in_face* *insert_in_edge*, *insert_outside_convex_hull*, *insert_outside_affine_hull* or *flip* on a valid Delaunay triangulation might lead to a triangulation which is no longer a Delaunay triangulation.

Queries

Vertex_handle *dt.nearest_vertex(Point p, Face_handle f=Face_handle())*

returns any nearest vertex of *p*. The implemented function begins with a location step and *f* may be used to initialize the location.

template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces, OutputItBoundaryEdges>

dt.get_conflicts_and_boundary(Point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,
Face_handle start)

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose circumcircle contains *p*. It outputs in the container pointed to by *eit* the the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are ouput in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a *std::pair* the resulting output iterators.

template <class OutputItFaces>
OutputItFaces *dt.get_conflicts(Point p, OutputItFaces fit, Face_handle start)*

same as above except that only the faces in conflict with *p* are output. The function returns the resulting output iterator.

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

dt.get_boundary_of_conflicts(Point p,
OutputItBoundaryEdges eit,
Face_handle start)

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This function outputs in the container pointed to by *eit*, the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are ouput in counterclockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns the resulting output iterator.

Voronoi diagram

The following member functions provide the elements of the dual Voronoi diagram.

<i>Point</i>	<i>dt.dual(Face_handle f)</i>	Returns the center of the circle circumscribed to face <i>f</i> . <i>Precondition: f</i> is not infinite
<i>Object</i>	<i>dt.dual(Edge e)</i>	returns a segment, a ray or a line supported by the bisector of the endpoints of <i>e</i> . If faces incident to <i>e</i> are both finite, a segment whose endpoints are the duals of each incident face is returned. If only one incident face is finite, a ray whose endpoint is the dual of the finite incident face is returned. Otherwise both incident faces are infinite and the bisector line is returned.
<i>Object</i>	<i>dt.dual(Edge_circulator ec)</i>	Idem
<i>Object</i>	<i>dt.dual(Edge_iterator ei)</i>	Idem
<i>template < class Stream></i> <i>Stream&</i>		
	<i>dt.draw_dual(Stream & ps)</i>	output the dual voronoi diagram to stream <i>ps</i> .

Predicates

<i>Oriented_side</i>	<i>dt.side_of_oriented_circle(Face_handle f, Point p)</i>	Returns the side of <i>p</i> with respect to the circle circumscribing the triangle associated with <i>f</i>
----------------------	------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------

└────────── *advanced* ─────────┘

Miscellaneous

The checking function *is_valid()* is also overwritten to additionally test the empty circle property.

<i>bool</i>	<i>dt.is_valid(bool verbose = false, int level = 0)</i>	tests the validity of the triangulation as a <i>Triangulation_2</i> and additionally tests the Delaunay property. This method is mainly useful for debugging Delaunay triangulation algorithms designed by the user.
-------------	----------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

└────────── *advanced* ─────────┘

See Also

CGAL::Triangulation_2<Traits,Tds>,
TriangulationDataStructure_2,
DelaunayTriangulationTraits_2,
Triangulation_hierarchy_2<Tr>.

Implementation

Insertion is implemented by inserting in the triangulation, then performing a sequence of Delaunay flips. The number of flips is $O(d)$ if the new vertex is of degree d in the new triangulation. For points distributed uniformly at random, insertion takes time $O(1)$ on average.

Removal calls the removal in the triangulation and then retriangulates the hole in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation.

After a point location step, the nearest neighbor is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

CGAL::Triangulation_2<Traits,Tds>::Locate_type

Definition

The enum *Locate_type* is defined by the *Triangulation_2<Traits,Tds>* class to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0, EDGE, FACET, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL};
```

The locate type is :

VERTEX when the located point coincides with a vertex of the triangulation

EDGE when the point is in the relative interior of an edge

FACET when the point is in the interior of a facet

OUTSIDE_CONVEX_HULL when the point is outside the convex hull but in the affine hull of the current triangulation

OUTSIDE_AFFINE_HULL when the point is outside the affine hull of the current triangulation.

CGAL::Triangulation_2<Traits,Tds>.

RegularTriangulationFaceBase_2

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighed points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal on some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation store those hidden points in special vertices called *hidden* vertices.

A hidden point can appear as vertex of the triangulation only when the two dimensional face where its point component is located (the face which hides it) is removed. Therefore we decided to store in each face of a regular triangulation the list of hidden vertices whose points are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base face of a regular triangulation has to be a model of the concept `RegularTriangulationFaceBase_2` , which refines the concept `TriangulationFaceBase_2` by adding in the face a list to store hidden vertices.

Refines

`TriangulationFaceBase_2`

Types

`typedef std::list<Vertex_handle>`

`Vertex_list;` An std list of hidden vertices.

Access Functions

`Vertex_list&` `rfb.vertex_list()` Returns a reference to the list of vertices hidden by the face.

Has Models

RegularTriangulationTraits_2

Definition

The concept `RegularTriangulationTraits_2` describe the requirements for the traits class of regular triangulations. It refines the concept `TriangulationTraits_2` providing the type `Weighted_point_2` and the *power-test* predicate on those weighted points. A weighted point is basically a point augmented with a scalar weight. It can be seen as a circle when the weight is interpreted as a square radius. The *power-test* on weighted points is the fundamental test to build regular triangulations as the *side_of_oriented_circle* test is the fundamental test of Delaunay triangulations.

Refines

`TriangulationTraits_2`

Types

`RegularTriangulationTraits_2::Bare_point` Another name for the point type.
`RegularTriangulationTraits_2::Weighted_point_2`

The weighted point type, it has to be a model of the concept `WeightedPoint`.

`RegularTriangulationTraits_2::Power_test_2` A predicate object type. Must provide the operators:
 — `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r, Weighted_point_2 s)` which is the power test for points p, q, r and s .
Precondition: the bare points corresponding to p, q, r are not collinear.
 — `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r)` which is the degenerated power test for collinear points p, q, r .
Precondition: the bare points corresponding to p, q, r are collinear and $p \neq q$.
 — `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q)` which is the degenerated power test for weighted points p and q whose corresponding bare-points are identical.
Precondition: the bare points corresponding to p and q are identical.

The following type/predicate is required if a call to `nearest_power_vertex` is issued:

`RegularTriangulationTraits_2::Compare_power_distance_2`

A predicate object type. Must provide the operator:
`Comparison_result operator()(Bare_point p, Weighted_point_2 q, Weighted_point_2 r)`, which compares the power distance between p and q to the power distance between p and r .

RegularTriangulationTraits_2::Construct_weighted_circumcenter_2

A constructor object which constructs the weighted circumcenter of three weighted points. Provides the operator *Bare_point operator()* (*Weighted_point_2 p*, *Weighted_point_2 q*, *Weighted_point_2 r*);

RegularTriangulationTraits_2::Construct_radical_axis_2

A constructor type which constructs the radical axis of two weighted points. Provides the operator : *Line_2 operator()* (*Weighted_point_2 p*, *Weighted_point_2 q*);

Creation

RegularTriangulationTraits_2 traits; default constructor.

RegularTriangulationTraits_2 traits(*RegularTriangulationTraits_2*);

copy constructor.

RegularTriangulationTraits_2&

traits = RegularTriangulationTraits_2

assignement operator

Access to predicate and constructors objects

RegularTriangulationVertexBase_2

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighed points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted point are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal on some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation store those hidden points in special vertices called *hidden* vertices.

A hidden point can appear as vertex of the triangulation only when the two dimensional face where its point component is located (the face which hides it) is removed. Therefore we decided to store in each face of a regular triangulation the list of hidden vertices whose points are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base vertex of a regular triangulation has to be a model of the concept `RegularTriangulationVertexBase_2`. The concept `RegularTriangulationVertexBase_2` refines the concept `TriangulationVertexBase_2`, just adding a boolean to mark if the vertex is a vertex of the triangulation or a hidden vertex.

Refines

`TriangulationVertexBase_2`

Access Functions

bool *rvb.is_hidden()* returns *true*, iff the vertex is hidden.

void *rvb.set_hidden(bool b)*

Mark the vertex as hidden or as not hidden.

CGAL::Regular_triangulation_2<Traits,Tds>

Definition

The class *Regular_triangulation_2<Traits,Tds>* is designed to maintain the regular triangulation of a set of weighted points.

Let $PW = \{(p_i, w_i), i = 1, \dots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i . Alternatively, each weighted point (p_i, w_i) can be regarded as a two dimensional sphere with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a planar partition such that each cell corresponds to sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere (p_j, w_j) in PW . The dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i, i = 1, \dots, n\}$ of center points and whose vertices are a subset of P . Such a triangulation is called a regular triangulation. The three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane whose powers with respect to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) are equal and less than the power of p with respect to any other sphere in PW .

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i) , and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) .

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ of the regular triangulation of PW is such that the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i) , (p_j, w_j) is (p_k, w_k) is positive or null. We call power test of the weighted point (p_l, w_l) with respect to the face $p_i p_j p_k$, the predicates testing the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i) , (p_j, w_j) is (p_k, w_k) . This power product is given by the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_l, w_l) with respect to $p_i p_j p_k$ is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW , is a regular triangulation of PW .

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i), i = 1, \dots, n\}$.

The vertices of the regular triangulation of a set of weighted points PW form only a subset of the set of center points of PW . Therefore the insertion of a weighted point in a regular triangulation does not necessarily imply the creation of a new vertex. If the new inserted point does not appear as a vertex in the regular triangulation, it is said to be hidden.

Hidden points are stored in special vertices called hidden vertices. A hidden point is considered as hidden by the facet of the triangulation where its point component is located : in fact, the hidden point can appear as vertex of the triangulation only if this facet is removed. Each face of a regular triangulation stores the list of hidden vertices whose points are located in the facet. When a facet is removed, points hidden by this facet are reinserted in the triangulation.

```
#include <CGAL/Regular_triangulation_2.h>
```

Parameters

The geometric traits parameter *Traits* has to be instantiated with a model of the concept *RegularTriangulationTraits_2*. The concept *RegularTriangulationTraits_2* refines the concept *TriangulationTraits_2* by adding the type *Weighted_point_2* to describe weighted points and the type *Power_test_2* to perform power tests on weighted points.

The *Tds* parameter has to be instantiated by a model of *TriangulationDataStructure_2*. The face base of a regular triangulation has to be a model of the concept *RegularTriangulationFaceBase_2*. while the vertex base class has to be a model of *RegularTriangulationVertexBase_2*. CGAL provides a default instantiation for the *Tds* parameter by the class *CGAL::Triangulation_data_structure_2 < CGAL::Regular_triangulation_vertex_base_2<Traits>, CGAL::Regular_Triangulation_face_base_2<Traits> >*.

typedef Traits::Ray           Ray;
```

```
typedef Traits::Bare_point     Bare_point;
```

```
typedef Traits::Weighted_point Weighted_point;
```

```
Regular_triangulation_2<Traits,Tds>:: All_vertices_iterator
```

An iterator that allows to enumerate the vertices that are not hidden.

```
Regular_triangulation_2<Traits,Tds>:: Finite_vertices_iterator
```

An iterator that allows to enumerate the finite vertices that are not hidden.

```
Regular_triangulation_2<Traits,Tds>:: Hidden_vertices_iterator;
```

An iterator that allows to enumerate the hidden vertices.

Creation

```
Regular_triangulation_2<Traits,Tds> rt( Traits gt = Traits());
```

Introduces an empty regular triangulation *rt*.

```
Regular_triangulation_2<Traits,Tds> rt( Regular_triangulation_2 rt);
```

Copy constructor.

Insertion and Removal

```
Vertex_handle rt.insert( Weighted_point p, Face_handle f=Face_handle())
```

inserts weighted point *p* in the regular triangulation. If the point *p* does not appear as a vertex of the triangulation, the returned vertex is a hidden vertex. If given the parameter *f* is used as an hint for the place to start the location process of point *p*.

```
Vertex_handle rt.insert( Weighted_point p, Locate_type lt, Face_handle loc, int li)
```

insert a weighted point *p* whose bare-point is assumed to be located in *lt,loc,li*.

```
Vertex_handle rt.push_back( Point p)      Equivalent to insert(p).
```

```
template < class InputIterator >  
int rt.insert( InputIterator first, InputIterator last)
```

inserts the weighted points in the range $[first, last)$. Returns the number of created vertices.

Precondition: The *value_type* of *first* and *last* is *Weighted_point*.

```
void rt.remove( Vertex_handle v)      removes the vertex from the triangulation.
```

Queries

```
template <class OutputItFaces, class OutputItBoundaryEdges, class OutputItHiddenVertices>  
CGAL::Triple<OutputItFaces,OutputItBoundaryEdges,OutputItHiddenVertices>
```

```
rt.get_conflicts_and_boundary_and_hidden_vertices( Weighted_point p,  
                                                    OutputItFaces fit,  
                                                    OutputItBoundaryEdges eit,  
                                                    OutputItHiddenVertices vit,
```

Face_handle start)

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. *OutputItHiddenVertices* is an output iterator with *Vertex_handle* as value type. This member function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose power circles have negative power wrt. *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. It inserts the vertices that would be hidden by *p* into the container pointed to by *vit*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a *CGAL::Triple* the resulting output iterators.

```
template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces,OutputItBoundaryEdges>
```

```
    rt.get_conflicts_and_boundary( Weighted_point p,
                                   OutputItFaces fit,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

same as above except that only the faces in conflict with *p* and the boundary edges of the conflict zone are output via the corresponding output iterators. The function returns in a *std::pair* the resulting output iterators.

```
template <class OutputItFaces, class OutputItHiddenVertices>
std::pair<OutputItFaces,OutputItHiddenVertices>
```

```
    rt.get_conflicts_and_hidden_vertices( Weighted_point p,
                                           OutputItFaces fit,
                                           OutputItHiddenVertices vit,
                                           Face_handle start)
```

same as above except that only the faces in conflict with *p* and the vertices that would be hidden by *p* are output via the corresponding output iterators. The function returns in a *std::pair* the resulting output iterators.

```
template <class OutputItBoundaryEdges, class OutputItHiddenVertices>
std::pair<OutputItBoundaryEdges,OutputItHiddenVertices>
```

```
    rt.get_boundary_of_conflicts_and_hidden_vertices( Weighted_point p,
                                                       OutputItBoundaryEdges eit,
                                                       OutputItHiddenVertices vit,
```

Face_handle start)

same as above except that only the vertices that would be hidden by p and the boundary of the zone in conflict with p are output via the corresponding output iterators. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through the incident face which is not in conflict with p . The function returns in a `std::pair` the resulting output iterators.

template <class OutputItFaces>
OutputItFaces

rt.get_conflicts(Point p, OutputItFaces fit, Face_handle start)

same as above except that only the faces in conflict with p are output. The function returns the resulting output iterator.

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

rt.get_boundary_of_conflicts(Point p, OutputItBoundaryEdges eit, Face_handle start)

same as above except that only the boundary edges of the conflict zone are output in counterclockwise order where each edge is described through the incident face which is not in conflict with p . The function returns the resulting output iterator.

template <class OutputItHiddenVertices>
OutputItHiddenVertices

rt.get_hidden_vertices(Point p, OutputItHiddenVertices vit, Face_handle start)

same as above except that only the vertices that would be hidden by p are output. The function returns the resulting output iterator.

Vertex_handle *rt.nearest_power_vertex(Bare_point p)*

Returns the vertex of the triangulation which is nearest to p with respect to the power distance. This means that the power of the query point p with respect to the weighted point in the nearest vertex is smaller than the power of p with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty.

Access functions

<i>int</i>	<i>rt.number_of_vertices()</i>	returns the number of finite vertices that are not hidden.
<i>int</i>	<i>rt.number_of_hidden_vertices()</i>	
		returns the number of hidden vertices.
<i>Hidden_vertices_iterator</i>	<i>rt.hidden_vertices_begin()</i>	
		starts at an arbitrary hidden vertex.
<i>Hidden_vertices_iterator</i>	<i>rt.hidden_vertices_end()</i>	past the end iterator for the sequence of hidden vertices.
<i>Finite_vertices_iterator</i>	<i>rt.finite_vertices_begin()</i>	starts at an arbitrary unhidden finite vertex
<i>Finite_vertices_iterator</i>	<i>rt.finite_vertices_end()</i>	Past-the-end iterator
<i>All_vertices_iterator</i>	<i>rt.all_vertices_end()</i>	starts at an arbitrary unhidden vertex.
<i>All_vertices_iterator</i>	<i>rt.all_vertices_begin()</i>	past the end iterator.

Dual power diagram

The following member functions provide the elements of the dual power diagram.

<i>Point</i>	<i>rt.weighted_circumcenter(Face_handle f)</i>	
		returns the center of the circle orthogonal to the three weighted points corresponding to the vertices of face <i>f</i> . <i>Precondition:</i> <i>f</i> is not infinite
<i>Point</i>	<i>rt.dual(Face_handle f)</i>	same as <i>weighted_circumcenter</i>
<i>Object</i>	<i>rt.dual(Edge e)</i>	If both incident faces are finite, returns a segment whose endpoints are the duals of each incident face. If only one incident face is finite, returns a ray whose endpoint is the dual of the finite incident face and supported by the line which is the bisector of the edge's endpoints. If both incident faces are infinite, returns the line which is the bisector of the edge's endpoints otherwise.
<i>Object</i>	<i>rt.dual(Edge_circulator ec)</i>	
		Idem
<i>Object</i>	<i>rt.dual(Edge_iterator ei)</i>	
		Idem
<i>template < class Stream></i> <i>Stream&</i>	<i>rt.draw_dual(Stream & ps)</i>	
		output the dual power diagram to stream <i>ps</i> .

Predicates

Oriented_side *rt.power_test(Face_handle f, Weighted_point p)*

Returns the power test of *p* with respect to the power circle associated with *f*

————— *advanced* —————

Miscellaneous

bool *rt.is_valid(bool verbose = false, int level = 0)*

Tests the validity of the triangulation as a *Triangulation_2* and additionally test the regularity of the triangulation. This method is useful to debug regular triangulation algorithms implemented by the user.

TriangulationFaceBase_2

Definition

The concept `TriangulationFaceBase_2` describes the requirements for the base face class of a triangulation data structure that is itself plugged into a basic triangulation or a Delaunay triangulation.

This concept refines the concept *TriangulationDSFaceBase_2* and could add geometric information. In fact, currently the triangulations of CGAL do not store any geometric information in the faces and, thus this concept is just equal to *TriangulationDSFaceBase_2* and only provided for symmetry with the vertex case.

TriangulationTraits_2

Definition

The concept `TriangulationTraits_2` describes the set of requirements to be fulfilled by any class used to instantiate the first template parameter of the class `Triangulation_2<Traits,Tds>`. This concept provides the types of the geometric primitives used in the triangulation and some function object types for the required predicates on those primitives.

Types

<code>TriangulationTraits_2:: Point_2</code>	The point type.
<code>TriangulationTraits_2:: Segment_2</code>	The segment type.
<code>TriangulationTraits_2:: Triangle_2</code>	The triangle type.
<code>TriangulationTraits_2:: Construct_segment_2</code>	A constructor object for <code>Segment_2</code> . Provides : <code>Segment_2 operator()(Point_2 p,Point_2 q)</code> , which constructs a segment from two points.
<code>TriangulationTraits_2:: Construct_triangle_2</code>	A constructor object for <code>Triangle_2</code> . Provides : <code>Triangle_2 operator()(Point_2 p,Point_2 q,Point_2 r)</code> , which constructs a triangle from three points.
<code>TriangulationTraits_2:: Compare_x_2</code>	Predicate object. Provides the operator : <code>Comparison_result operator()(Point p, Point q)</code> which returns <code>SMALLER</code> , <code>EQUAL</code> or <code>LARGER</code> according to the <i>x</i> -ordering of points <i>p</i> and <i>q</i> .
<code>TriangulationTraits_2:: Compare_y_2</code>	Predicate object. Provides the operator : <code>Comparison_result operator()(Point p, Point q)</code> which returns (<code>SMALLER</code> , <code>EQUAL</code> or <code>LARGER</code>) according to the <i>y</i> -ordering of points <i>p</i> and <i>q</i> .
<code>TriangulationTraits_2:: Orientation_2</code>	Predicate object. Provides the operator : <code>Orientation operator()(Point p, Point q, Point r)</code> which returns <code>LEFT_TURN</code> , <code>RIGHT_TURN</code> or <code>COLLINEAR</code> depending on <i>r</i> being, with respect to the oriented line <i>pq</i> , on the left side , on the right side or on the line.
<code>TriangulationTraits_2:: Side_of_oriented_circle_2</code>	Predicate object. Must provide the operator <code>Oriented_side operator()(Point p, Point q, Point r, Point s)</code> which takes four points <i>p,q,r,s</i> as arguments and returns <code>ON_POSITIVE_SIDE</code> , <code>ON_NEGATIVE_SIDE</code> or <code>ON_ORIENTED_BOUNDARY</code> according to the position of points <i>s</i> with respect to the oriented circle through through <i>p,q</i> and <i>r</i> . This type is required only if the function <code>side_of_oriented_circle(Face_handle f, Point p)</code> is called.

TriangulationTraits_2::Construct_circumcenter_2

Constructor object. Provides the operator :
Point operator()(Point p, Point q, Point r)
which returns the circumcenter of the three points *p*, *q*
and *r*. This type is required only if the function *Point*
circumcenter(Face_handle f) is called.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.
TriangulationTraits_2 traits; default constructor.
TriangulationTraits_2 traits(gtr); Copy constructor

TriangulationTraits_2 traits = gtr Assignment operator.

Predicate functions

The following functions give access to the predicate and constructor objects.

Construct_segment_2 traits.construct_segment_2_object()

Construct_triangle_2 traits.construct_triangle_2_object()

Comparison_x_2 traits.compare_x_2_object()

Comparison_y_2 traits.compare_y_2_object()

Orientation_2 traits.orientation_2_object()

Side_of_oriented_circle_2

traits.side_of_oriented_circle_2_object()

Required only if *side_of_oriented_circle* is called.

Construct_circumcenter_2

traits.construct_circumcenter_2_object()

Required only if *circumcenter* is called.

TriangulationVertexBase_2

Definition

The concept `TriangulationVertexBase_2` describes the requirements for the vertex base class of a triangulation data structure to be plugged in a basic, Delaunay or constrained triangulations.

The concept `TriangulationVertexBase_2` refines the concept `TriangulationDSVertexBase_2` adding geometric information : the vertex base of a triangulation stores a point.

Refines

`TriangulationDSVertexBase_2`

Types

`TriangulationVertexBase_2::Point`

Must be the same as the point type `TriangulationTraits_2::Point_2` defined by the geometric traits class of the triangulation.

Creation

`TriangulationVertexBase_2 v(Point p);` constructs a vertex embedded in point p .

`TriangulationVertexBase_2 v(Point p, Face_handle f);`
constructs a vertex embedded in point p and pointing on face f .

Access Functions

`Point v.point()` returns the point.

Setting

`void v.set_point(Point p)`
sets the point.

I/O

`istream& istream& is >> & v`

Inputs the non-combinatorial information given by the vertex: the point and other possible information.

ostream&

ostream& os << v

Outputs the non combinatorial operation given by the vertex: the point and other possible information.

Has Models

CGAL::TriangulationVertexBase_2<Traits>.

CGAL::Triangulation_2<Traits,Tds>

Definition

The class *Triangulation_2<Traits,Tds>* is the basic class designed to handle triangulations of set of points *A* in the plane.

Such a triangulation has vertices at the points of *A* and its domain covers the convex hull of *A*. It can be viewed as a planar partition of the plane whoses bounded faces are triangular and cover the convex hull of *A*. The single unbounded face of this partition is the complementary of the convex hull of *A*.

In many applications, it is convenient to deal only with triangular faces. Therefore, we add to the triangulation a fictitious vertex, called the *infinite vertex* and we make each convex hull edge incident to an *infinite* face having as third vertex the *infinite vertex*. In that way, each edge is incident to exactly two faces and special cases at the boundary of the convex hull are simpler to deal with.

Figure 20.9: The infinite vertex.

The class *Triangulation_2<Traits,Tds>* implements this point of view and therefore considers the triangulation of the set of points as a set of triangular, finite and infinite faces. Although it is convenient to draw a triangulation as in figure 20.9, note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it or on an infinite face.

A triangulation is a collection of vertices and faces that are linked together through incidence and adjacency relations. Each face give access to its three incident vertices and to its three adjacent faces. Each vertex give access to one of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbor of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by *i* is opposite to the vertex with the same index.

The triangulation class offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. Thus, for example the neighbor *neighbor(cw(i))* is the neighbor of *f* which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f* (see Figure 20.10).

```
#include <CGAL/Triangulation_2.h>
```

Parameters

The class *Triangulation_2<Traits,Tds>* has two template parameters. The first one *Traits* is the geometric traits, it is to be instantiated by a model of the concept *TriangulationTraits_2*.

Figure 20.10: Vertices and neighbors.

The second parameter is the triangulation data structure, it has to be instantiated by a model of the concept *TriangulationDataStructure_2*. By default, the triangulation data structure is instantiated by `CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2<Gt> >>`.

Inherits From

Triangulation_cw_ccw_2 This class provides the functions *cw(i)* et *ccw(i)*.

Types

<code>typedef Traits</code>	<code>Geom_traits;</code>	the traits class.
<code>typedef Tds</code>	<code>Triangulation_data_structure;</code>	the triangulation data structure type.
<code>typedef Traits::Point_2t</code>	<code>Point;</code>	the point type
<code>typedef Traits::Segment_2</code>	<code>Segment;</code>	the segment type
<code>typedef Traits::Triangle_2</code>	<code>Triangle;</code>	the triangle type
<code>typedef Tds::Vertex</code>	<code>Vertex;</code>	the vertex type.
<code>typedef Tds::Face</code>	<code>Face;</code>	the face type.
<code>typedef Tds::Edge</code>	<code>Edge;</code>	the edge type.
<code>typedef Tds::size_type</code>	<code>size_type;</code>	Size type (an unsigned integral type)
<code>typedef Tds::difference_type</code>	<code>difference_type;</code>	Difference type (a signed integral type)

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. The handles are models of the concept *Handle* which basically offers the two dereference operators `*` and `->`. The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to handles with the same value type, so that whenever a handle appear in the parameter list of a function, an appropriate iterator or circulator can be passed as well.

The edges of the triangulation can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non mutable.

In the following, we called *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the triangulation is said to be *finite*. Some iterators (the *All* iterators

) allows to visit finite or infinite feature while others (the *Finite* iterators) visit only finite features. Circulators visit infinite features as well as finite ones.

<code>typedef Tds::Vertex_handle</code>	<code>Vertex_handle;</code>	handle to a vertex
<code>typedef Tds::Face_handle</code>	<code>Face_handle;</code>	handle to a face
<code>typedef Tds::Face_iterator</code>	<code>All_faces_iterator;</code>	iterator over all faces.
<code>typedef Tds::Edge_iterator</code>	<code>All_edges_iterator;</code>	iterator over all edges
<code>typedef Tds::Vertex_iterator</code>	<code>All_vertices_iterator;</code>	iterator over all vertices
<code>Triangulation_2<Traits,Tds>:: Finite_faces_iterator</code>		iterator over finite faces.
<code>Triangulation_2<Traits,Tds>:: Finite_edges_iterator</code>		iterator over finite edges.
<code>Triangulation_2<Traits,Tds>:: Finite_vertices_iterator</code>		iterator over finite vertices.
<code>Triangulation_2<Traits,Tds>:: Point_iterator</code>		iterator over the points corresponding the finite vertices of the triangulation.
<code>Triangulation_2<Traits,Tds>:: Line_face_circulator</code>		circulator over all faces intersected by a line.
<code>Triangulation_2<Traits,Tds>:: Face_circulator</code>		circulator over all faces incident to a given vertex.
<code>Triangulation_2<Traits,Tds>:: Edge_circulator</code>		circulator over all edges incident to a given vertex.
<code>Triangulation_2<Traits,Tds>:: Vertex_circulator</code>		circulator over all vertices incident to a given vertex.

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0, EDGE, FACE, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL};
```

The locate type is *OUTSIDE_CONVEX_HULL* when the point is outside the convex hull but in the affine hull of the current triangulation.

The locate type is *OUTSIDE_AFFINE_HULL* when the point is outside the affine hull of the current triangulation.

Creation

```
Triangulation_2<Traits,Tds> t;           default constructor.
Triangulation_2<Traits,Tds> t( Traits gt = Traits());
```

Introduces an empty triangulation *t*.

Triangulation_2<*Traits*,*Tds*> *t*(*Triangulation_2 tr*);

Copy constructor. All the vertices and faces are duplicated. After the copy, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

Triangulation_2 *t = tr*

Assignment. All the vertices and faces are duplicated. After the assignment, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

void *t.swap(Triangulation_2& tr)*

The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t = tr* or to *t(tr)* if *tr* is deleted after that.

void *t.clear()*

Deletes all faces and finite vertices resulting in an empty triangulation.

Access Functions

Geom_traits *t.geom_traits()*
TriangulationDataStructure_2

Returns a const reference to the triangulation traits object.

t.tds()

Returns a const reference to the triangulation data structure.

————— *advanced* —————

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_2&

t.tds()

Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

————— *advanced* —————

int *t.dimension()*

Returns the dimension of the convex hull.

size_type *t.number_of_vertices()*

Returns the number of finite vertices.

size_type *t.number_of_faces()*

Returns the number of finite faces.

Face_handle *t.infinite_face()*

a face incident to the *infinite_vertex*.

Vertex_handle *t.infinite_vertex()*

the *infinite_vertex*.

Vertex_handle *t.finite_vertex()*

a vertex distinct from the *infinite_vertex*.

Predicates

The class *Triangulation_2*<*Traits*,*Tds*> provides methods to test the finite or infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face).

bool t.is_infinite(Vertex_handle v) *true* iff *v* is the *infinite_vertex*.
bool t.is_infinite(Face_handle f) *true* iff face *f* is infinite.
bool t.is_infinite(Face_handle f, int i) *true* iff edge (*f,i*) is infinite.
bool t.is_infinite(Edge e) *true* iff edge *e* is infinite.
bool t.is_infinite(Edge_circulator ec) *true* iff edge **ec* is infinite.
bool t.is_infinite(Edge_iterator ei) *true* iff edge **ei* is infinite.

bool t.is_edge(Vertex_handle va, Vertex_handle vb)
true if there is an edge having *va* and *vb* as vertices.

bool t.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle& fr, int & i)
as above. In addition, if *true* is returned, the edge with vertices *va* and *vb* is the edge *e=(fr,i)* where *fr* is a handle to the face incident to *e* and on the right side of *e* oriented from *va* to *vb*.

bool t.includes_edge(Vertex_handle va, Vertex_handle & vb, Face_handle& fr, int & i)
true if the line segment from *va* to *vb* includes an edge *e* incident to *va*. If *true*, *vb* becomes the other vertex of *e*, *e* is the edge (*fr,i*) where *fr* is a handle to the face incident to *e* and on the right side *e* oriented from *va* to *vb*.

bool t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)
true if there is a face having *v1*, *v2* and *v3* as vertices.

bool t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)
as above. In addition, if *true* is returned, *fr* is a handle to the face with *v1*, *v2* and *v3* as vertices.

Queries

The class *Triangulation_2<Traits,Tds>* provides methods to locate a given point with respect to a triangulation. It also provides methods to locate a point with respect to a given finite face of the triangulation.

Face_handle t.locate(Point query, Face_handle f = Face_handle())

If the point *query* lies inside the convex hull of the points, a face that contains the query in its interior or on its boundary is returned.

If the point *query* lies outside the convex hull of the triangulation but in the affine hull, the returned face is an infinite face which is a proof of the point's location :

- for a two dimensional triangulation, it is a face (∞, p, q) such that *query* lies to the left of the oriented line *pq* (the rest of the triangulation lying to the right of this line).

- for a degenerate one dimensional triangulation it is the (degenerate one dimensional) face $(\infty, p, NULL)$ such that *query* and the triangulation lie on either side of *p*.

If the point *query* lies outside the affine hull, the returned *Face_handle* is *NULL*.

The optional *Face_handle* argument, if provided, is used as a hint of where the locate process has to start its search.

Face_handle *t.locate(Point query, Locate_type& lt, int& li, Face_handle h =Face_handle())*

Same as above. Additionally, the parameters *lt* and *li* describe where the query point is located. The variable *lt* is set to the locate type of the query. If *lt*==*VERTEX* the variable *li* is set to the index of the vertex, and if *lt*==*EDGE* *li* is set to the index of the vertex opposite to the edge. Be careful that *li* has no meaning when the query type is *FACE*, *OUTSIDE_CONVEX_HULL*, or *OUTSIDE_AFFINE_HULL* or when the triangulation is 0-dimensional.

Oriented_side *t.oriented_side(Face_handle f, Point p)*

Returns on which side of the oriented boundary of *f* lies the point *p*.
Precondition: *f* is finite.

Oriented_side *t.side_of_oriented_circle(Face_handle f, Point p)*

Returns on which side of the circumcircle of face *f* lies the point *p*. The circle is assumed to be counterclockwisely oriented, so its positive side correspond to its bounded side. This predicate is available only if the corresponding predicates on points is provided in the geometric traits class.

Modifiers

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

void *t.flip(Face_handle f, int i)*

Exchanges the edge incident to *f* and *f->neighbor(i)* with the other diagonal of the quadrilateral formed by *f* and *f->neighbor(i)*.
Precondition: The faces *f* and *f->neighbor(i)* are finite faces and their union form a convex quadrilateral.

Vertex_handle *t.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex.
 If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.
 If point *p* is on an edge, the two incident faces are split in two.
 If point *p* is strictly inside a face of the triangulation, the face is split in three.
 If point *p* is strictly outside the convex hull, *p* is linked to all visible points on the convex hull to form the new triangulation.
 At last, if *p* is outside the affine hull (in case of degenerate 1-dimensional or 0-dimensional triangulations), *p* is linked all the other vertices to form a triangulation whose dimension is increased by one. The last argument *f* is an indication to the underlying locate algorithm of where to start.

Figure 20.11: Insertion of a point on an edge.

Figure 20.12: Insertion in a face.

Vertex_handle *t.insert(Point p, Locate_type lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by (lt, loc, i) (see the description of the *locate* method above.)

Vertex_handle *t.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
int *t.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.

Precondition: The *value_type* of *InputIterator* is *Point*.

void *t.remove(Vertex_handle v)*

Removes the vertex from the triangulation. The created hole is retriangulated.

Precondition: Vertex *v* must be finite.

— *advanced* —

The following member functions offer more specialized versions of the insertion or removal operations to be used when one knows to be in the corresponding case.

Figure 20.13: Insertion outside the convex hull.

Figure 20.14: Removal

Vertex_handle *t.insert_first(Point p)*

Inserts the first finite vertex .

Vertex_handle *t.insert_second(Point p)*

Inserts the second finite vertex .

Vertex_handle *t.insert_in_face(Point p, Face_handle f)*

Inserts vertex v in face f . Face f is modified, two new faces are created.

Precondition: The point in vertex v lies inside face f .

Vertex_handle *t.insert_in_edge(Point p, Face_handle f, int i)*

Inserts vertex v in edge i of f .

Precondition: The point in vertex v lies on the edge opposite to the vertex i of face f .

Vertex_handle *t.insert_outside_convex_hull(Point p, Face_handle f)*

Inserts a point which is outside the convex hull but in the affine hull.

Precondition: The handle f points to a face which is a proof of the location of p , see the description of the *locate* method above.

Vertex_handle *t.insert_outside_affine_hull(Point p)*

Inserts a point which is outside the affine hull.

void *t.remove_degree_3(Vertex_handle v)*

Removes a vertex of degree three. Two of the incident faces are destroyed, the third one is modified.

Precondition: Vertex v is a finite vertex with degree three.

void *t.remove_second(Vertex_handle v)*

Removes the before last finite vertex.

void *t.remove_first(Vertex_handle v)*

Removes the last finite vertex.

The following fonctions are mainly intended to be used in conjunction with the *find_conflicts()* member fonctions of Delaunay and constrained Delaunay triangulations to perform insertions.

```
template<class EdgeIt>
Vertex_handle t.star_hole( Point p, EdgeIt edge_begin, EdgeIt edge_end)
```

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end]$. Returns a handle to the new vertex.

```
template<class EdgeIt, class FaceIt>
Vertex_handle t.star_hole( Point p,
                          EdgeIt edge_begin,
                          EdgeIt edge_end,
                          FaceIt face_begin,
                          FaceIt face_end)
```

same as above, except that the algorithm first recycles faces in the sequence $[face_begin, face_end]$ and create new ones only when the sequence is exhausted.

_____ advanced _____

Traversal of the Triangulation

A triangulation can be seen as a container of faces and vertices. Therefore the triangulation provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex
<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_end()</i>	Past-the-end iterator
<i>Finite_edges_iterator</i>	<i>t.finite_edges_begin()</i>	Starts at an arbitrary finite edge
<i>Finite_edges_iterator</i>	<i>t.finite_edges_end()</i>	Past-the-end iterator
<i>Finite_faces_iterator</i>	<i>t.finite_faces_begin()</i>	Starts at an arbitrary finite face
<i>Finite_faces_iterator</i>	<i>t.finite_faces_end()</i>	Past-the-end iterator
<i>Point_iterator</i>	<i>t.points_begin()</i>	
<i>Point_iterator</i>	<i>t.points_end()</i>	Past-the-end iterator

The following iterators allow respectively to visit all (finite or infinite) faces, edges and vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>All_vertices_iterator</i>	<i>t.all_vertices_begin()</i>	Starts at an arbitrary vertex
<i>All_vertices_iterator</i>	<i>t.all_vertices_end()</i>	Past-the-end iterator
<i>All_edges_iterator</i>	<i>t.all_edges_begin()</i>	Starts at an arbitrary edge

<i>All_edges_iterator</i>	<i>t.all_edges_end()</i>	Past-the-end iterator
<i>All_faces_iterator</i>	<i>t.all_faces_begin()</i>	Starts at an arbitrary face
<i>All_faces_iterator</i>	<i>t.all_faces_end()</i>	Past-the-end iterator

Line Face Circulator

The triangulation defines a circulator that allows to visit all faces that are intersected by a line. A face f is considered as being intersected by the oriented line l if either:

- f is a finite face whose interior intersects l , or
- f is a finite face with an edge collinear with l and lies to the left of l , or
- f is an infinite face incident to a convex hull edge whose interior is intersected by l , or
- f is an infinite face incident to a convex hull vertex lying on l and the finite edge of f lies to the left of l .

The circulator has a singular value if the line l intersect no finite face of the triangulation. This circulator is non-mutable and bidirectional. Its value type is *Face*.

Line_face_circulator *t.line_walk(Point p, Point q, Face_handle f = Face_handle())*

This function returns a circulator that allows to visit the faces intersected by the line pq . If there is no such face the circulator has a singular value.

The starting point of the circulator is the face f , or the first finite face traversed by l , if f is omitted.

The circulator wraps around the *infinite_vertex* : after the last traversed finite face, it steps through the infinite face adjacent to this face then through the infinite face adjacent to the first traversed finite face then through the first finite traversed face again.

Precondition: Points p and q must be different points.

Precondition: If $f \neq \text{NULL}$, it must point to a finite face and the point p must be inside or on the boundary of f .

Figure 20.15 illustrates which finite faces are enumerated. Lines l_1 and l_2 have no face to their left. Lines l_3 and l_4 have faces to their left. Note that the finite faces that are only vertex incident to lines l_3 and l_4 are not enumerated.

A line face circulator is invalidated if the face the circulator refers to is changed.

Face, Edge and Vertex Circulators

The triangulation also provides circulators that allows to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge or a vertex circulator are invalidated by any modification of one of the two faces incident to the edge pointed to.

Face_circulator *t.incident_faces(Vertex_handle v)*

Starts at an arbitrary face incident to v .

Figure 20.15: The line face circulator.

<i>Face_circulator</i>	<i>t.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .
<i>Edge_circulator</i>	<i>t.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>t.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .
<i>Vertex_circulator</i>	<i>t.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>t.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

<i>Face_circulator</i>	<i>t.incident_faces(t.infinite_vertex())</i>
<i>Face_circulator</i>	<i>t.incident_faces(t.infinite_vertex(), Face_handle f)</i>
<i>Edge_circulator</i>	<i>t.incident_edges(t.infinite_vertex())</i>
<i>Edge_circulator</i>	<i>t.incident_edges(t.infinite_vertex(), Face_handle f)</i>
<i>Vertex_circulator</i>	<i>t.incident_vertices(t.infinite_vertex() v)</i>
<i>Vertex_circulator</i>	<i>t.incident_vertices(t.infinite_vertex(), Face_handle f)</i>

Miscellaneous

<i>int</i>	<i>t.ccw(int i)</i>	Returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>t.cw(int i)</i>	Returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>Triangle</i>		
	<i>t.triangle(Face_handle f)</i>	Returns the triangle formed by the three vertices of <i>f</i> . <i>Precondition:</i> The face is finite.
<i>Segment</i>	<i>t.segment(Face_handle f, int i)</i>	Returns the line segment formed by the vertices <i>ccw(i)</i> and <i>cw(i)</i> of face <i>f</i> . <i>Precondition:</i> $0 \leq i \leq 2$. The vertices <i>ccw(i)</i> and <i>cw(i)</i> of <i>f</i> are finite.
<i>Segment</i>	<i>t.segment(Edge e)</i>	Returns the line segment corresponding to edge <i>e</i> . <i>Precondition:</i> <i>e</i> is a finite edge
<i>Segment</i>	<i>t.segment(Edge_circulator ec)</i>	Returns the line segment corresponding to edge <i>*ec</i> . <i>Precondition:</i> <i>*ec</i> is a finite edge.
<i>Segment</i>	<i>t.segment(Edge_iterator ei)</i>	Returns the line segment corresponding to edge <i>*ei</i> . <i>Precondition:</i> <i>*ei</i> is a finite edge.
<i>Point</i>	<i>t.circumcenter(Face_handle f)</i>	Compute the circumcenter of the face pointed to by <i>f</i> . This function is available only if the corresponding function is provided in the geometric traits.

— advanced —

Setting

void *t.set_infinite_vertex(Vertex_handle v)*

Checking

The responsibility of keeping a valid triangulation belongs to the users if advanced operations are used. Obviously the advanced user, who implements higher levels operations may have to make a triangulation invalid at some times. The following method is provided to help the debugging.

bool *t.is_valid(bool verbose = false, int level = 0)*

Checks the combinatorial validity of the triangulation and also the validity of its geometric embedding. This method is mainly a debugging help for the users of advanced features.

— advanced —

I/O

The I/O operators are defined for *iostream*. The format for the *iostream* is an internal format.

ostream& *ostream& os << T*

Inserts the triangulation *t* into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

istream& *istream*& *is* >> *T* Reads a triangulation from stream *is* and assigns it to *t*.
Precondition: The extract operator must be defined for *Point*.

The information output in the *iostream* is:

- the dimension, the number of vertices (including the infinite one), and the number of faces (including infinite ones).
- for each vertex (except the infinite vertex), the non combinatorial information stored in that vertex (point, etc.).
- for each faces, the indices of its vertices and the non combinatorial information (if any) in this face. - for each face again the indices of the neighboring faces.

The index of an item (vertex of face) is the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

CGAL also provides stream operators << to draw triangulations on *CGAL::Window_stream*, the LEDA based graphic package, and on *CGAL::Qt_widget*, the Qt based graphic package. These operators requires respectively the include statements :

```
#include CGAL/IO/Window_stream.h
```

```
#include CGAL/IO/Qt_widget_Triangulation_2.h
```

See the chapters on *Window_stream* and on *Qt_widget* in the Support Library manual.

Implementation

Locate is implemented by a line walk from a vertex of the face given as optional parameter (or from a finite vertex of *infinite_face()* if no optional parameter is given). It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random.

Insertion of a point is done by locating a face that contains the point, and then splitting this face. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and retriangulating the hole. Removal takes time $O(d^2)$ in the worst case, if d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

CGAL::Triangulation_cw_ccw_2

Definition

The class *Triangulation_cw_ccw_2* offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. This works also for neighbor indexes. Thus, for example the neighbor *neighbor(cw(i))* of a face *f* is the neighbor which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f*.

Many of the classes in the triangulation package inherit from *Triangulation_cw_ccw_2*. This is for instance the case for *CGAL::Triangulation_2<Traits,Tds>::Face*. Thus, for example the neighbor *neighbor(cw(i))* of a face *f* is the neighbor which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f*.

```
#include <CGAL/Triangulation_2.h>
```

Creation

<i>Triangulation_cw_ccw_2</i>	<i>a</i> ;	default constructor.
-------------------------------	------------	----------------------

Operations

<i>int</i>	<i>a.ccw(const int i)</i>	returns the index of the neighbor or vertex that is next to the neighbor or vertex with index <i>i</i> in counterclockwise order around a face.
<i>int</i>	<i>a.cw(const int i)</i>	returns the index of the neighbor or vertex that is next to the neighbor or vertex with index <i>i</i> in counterclockwise order around a face.

CGAL::Triangulation_euclidean_traits_xy_3<*K*>

CGAL::Triangulation_euclidean_traits_xy_3<K>

Definition

The class *Triangulation_euclidean_traits_xy_3<K>* is a geometric traits class which allows to triangulate a terrain. This traits class is designed to build a two dimensional triangulation embedded in 3D space, i.e. a triangulated surface, such that its on the *xy* plane is a Delaunay triangulation. This is a usual construction for GIS terrains. Instead of really projecting the 3D points and maintaining a mapping between each point and its projection (which costs space and is error prone) the class *Triangulation_euclidean_traits_xy_3<K>* supplies geometric predicates that ignore the *z*-coordinate of the points.

The class is a model of the concept *DelaunayTriangulationTraits_2* except that it does not provide the type and constructors required to build the dual Voronoi diagram.

Parameters

The template parameter *K* has to be instantiated by a model of the *Kernel* concept. *Triangulation_euclidean_traits_xy_3<K>* uses types and predicates defined in *K*.

```
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
```

Types

```
typedef Point_3<K>      Point_2;
typedef Segment_3<K>    Segment_2;

typedef Triangle_3<K>    Triangle_2;
```

The following predicates and constructor types are provided

Triangulation_euclidean_traits_xy_3<K>::Construct_segment_2

A constructor object for *Segment_2*. Provides :
Segment_2 operator()(Point_2 p, Point_2 q),
 which constructs a segment from two points.

Triangulation_euclidean_traits_xy_3<K>::Construct_triangle_2

A constructor object for *Triangle_2*. Provides :
Triangle_2 operator()(Point_2 p, Point_2 q, Point_2 r),
 which constructs a triangle from three points.

Triangulation_euclidean_traits_xy_3<K>::Compare_x_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
 which returns *SMALLER*, *EQUAL* or *LARGER* according to the *x*-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Compare_y_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
which returns (*SMALLER*, *EQUAL* or *LARGER*) according to the y-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Orientation_2

Predicate object. Provides the operator :
Orientation operator()(Point_2 p, Point_2 q, Point_2 r)
which returns *LEFT_TURN*, *RIGHT_TURN* or *COLLINEAR* according to the position of the projection of *r* with respect to the projection of the oriented line *pq*.

Triangulation_euclidean_traits_xy_3<K>:: Side_of_oriented_circle_2

Predicate object. Provides the operator : *Oriented_side operator()(Point_2 p, Point_2 q, Point_2 r, Point_2 s)* which takes four points *p, q, r, s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of the projection of points with respect to the oriented circle through the projections of *p, q* and *r*.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.

Triangulation_euclidean_traits_xy_3<K> traits;

default constructor.

Triangulation_euclidean_traits_xy_3<K> traits(Triangulation_euclidean_traits_xy_3 tr);

Copy constructor.

Triangulation_euclidean_traits_xy_3 traits = Triangulation_euclidean_traits_xy_3 tr

Assignment operator.

Access to predicate objects

The following access functions are provided

<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_triangle_2</i>	<i>traits.construct_triangle_2_object()</i>
<i>Comparison_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Comparison_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Orientation_2</i>	<i>traits.orientation_2_object()</i>
<i>Side_of_oriented_circle_2</i>	<i>traits.side_of_oriented_circle_2_object()</i>

CGAL::Triangulation_face_base_2<Traits,Fb>

Definition

The class *Triangulation_face_base_2*<Traits,Fb> is a model for the concept *TriangulationFaceBase_2*. It is the default face base class for basic and Delaunay triangulation.

These default base class can be used directly or can serve as a base to derive other base classes with some additional attribute (a color for example) tuned for specific applications.

Parameters

The first template parameter of *Triangulation_face_base_2*<Traits,Fb> is a geometric traits class. The geometric traits is actually not used by the class.

The second template parameter has to be a model of the concept *TriangulationDSFaceBase_2* and will serve as a base class for *Triangulation_face_base_2*<Traits,Fb> . CGAL provides a default instantiation for this parameter which is *Triangulation_ds_face_base_2*<>.

```
#include <CGAL/Triangulation_face_base_2.h>

Definition

The class *Triangulation_face_base_with_info_2<Info,Traits,Fb>* is a model of the concept *TriangulationFaceBase_2* to be plugged into the triangulation data structure of a triangulation class. It provides an easy way to add some user defined information in the faces of a triangulation.

```
#include <CGAL/Triangulation_face_base_with_info_2.h>
```

Parameters

The first template argument is the information the user would like to add to a face. It has to be *DefaultConstructible* and *Assignable*.

The second template argument is a geometric traits class and is actually not used in *Triangulation_face_base_with_info_2<Info,Traits,Fb>* .

The third parameter is a face base class from which *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives.

Inherits From

Fb

Is Model for the Concepts

Because *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives from the class instantiating its third parameter, it will be a model of the same face base concept as its parameter : *TriangulationFaceBase_2*, *ConstrainedTriangulationFaceBase_2* , or *RegularTriangulationFaceBase_2*

Types

```
typedef Info          Info;
```

Access Functions

<code>const Info& f.info() const</code>	Returns a const reference to the object of type <i>Info</i> stored in the face.
<code>Info& f.info()</code>	Returns a reference to the object of type <i>Info</i> stored in the face.

CGAL::Triangulation_hierarchy_2<Tr>

Definition

The class *Triangulation_hierarchy_2<Tr>* implements a triangulation augmented with a data structure which allows fast point location queries.

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level.

Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level.

Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behaviour when it is built for Delaunay triangulations. However it can be used as well for other triangulations. The class *Triangulation_hierarchy_2<Tr>* is templated by a parameter which is to be instantiated by anyone of the CGAL triangulation classes.

```
#include <CGAL/Triangulation_hierarchy_2.h>
```

Inherits From

Tr

Types

The class *Triangulation_hierarchy_2<Tr>* inherits the types from its base triangulation class *Tr*.

The class *Triangulation_hierarchy_2<Tr>* offers exactly the same functionalities as the triangulation *Tr* does. Location queries are overloaded to benefit from the data structure. Modifiers (insertion, removal) are overloaded to take care of updating the data structure.

Be careful that I/O operations are not overloaded. Writing a *Triangulation_hierarchy_2<Tr>* into a file writes only the lowest level triangulation and drop the hierarchy and reading it from a file results in a triangulation whose efficiency will be that of an ordinary triangulation.

21.1 Definition

A triangulation data structure is a data structure designed to handle the representation of a two dimensional triangulation. The concept of triangulation data structure was primarily designed to serve as a data structure for CGAL 2D triangulation classes which are triangulations embedded in a plane. However it appears that the concept is more general and can be used for any orientable triangulated surface without boundary, whatever may be the dimensionality of the space the triangulation is embedded in.

21.1.1 A data structure based on faces and vertices

The representation of CGAL 2D triangulations is based on faces and vertices, Edges are only implicitly represented trough the adjacency relations between two faces.

The triangulation data structure can be seen as a container for faces and vertices maintaining incidence and adjacency relations among them.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

Figure 21.1: Vertices and neighbors.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 21.1, the functions $ccw(i)$ and $cw(i)$ shown on this figure compute respectively $i + 1$ and $i - 1$ modulo 3

Each edge has two implicit representations : the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f .

This kind of representation of simplicial complexes extends in any dimension. More precisely, in dimension d , the data structure will explicitly represents cells (i. e. faces of maximal dimension) and vertices (i. e. faces of dimension 0). All faces of dimension between 1 and $d - 1$ will have an implicit representation. The 2D triangulation data structure can represent simplicial complexes of dimension 2, 1 or 0.

21.1.2 The set of faces and vertices

The set of faces maintained by a 2D triangulation data structure is such that each edge is incident to two faces. In other words, the set of maintained faces is topologically equivalent to a two-dimensional triangulated sphere.

This rule extends to lower dimensional triangulation data structure arising in degenerate cases or when the triangulations have less than three vertices. A one dimensional triangulation structure maintains a set of vertices and edges which forms a ring topologically equivalent to a 1-sphere.

A zero dimensional triangulation data structure only includes two adjacent vertices that is topologically equivalent to a 0-sphere.

21.2 The Concept of Triangulation Data Structure

A model of *TriangulationDataStructure_2* can be seen has a container for the faces and vertices of the triangulation. This class is also responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure maintains proper incidence and adjacency relations among the vertices and faces of a triangulation while combinatorial modifications of the triangulation are performed. The term combinatorial modification refers to operations which do not involve any knowledge about the geometric embedding of the triangulation. For example, the insertion of a new vertex in a given face, or in a given edge, the suppression of a vertex of degree three, the flip of two edge are examples of combinatorial operation performed at the data structure level.

The triangulation data structure is required to provide :

Figure 21.2: Insertion of a new vertex, splitting a face

- the types *Vertex* and *Face* for the vertices and faces of the triangulations
- the type *Vertex_handle* and *Face_handle* which are models of the concept *Handle* and through which the vertices and faces are accessed.
- iterators to visit all the vertices, edges and faces of the triangulation,
- circulators to visit all the vertices, edges and faces incident to a given vertex

The triangulation data structure is responsible for the creation and removal of faces and vertices (memory management). It provides function that gives the number of faces, edges and vertices of the triangulation.

The triangulation data structure provides member functions to perform the following combinatorial transformation of the triangulation:

- flip of two adjacent faces,
- addition of a new vertex splitting a given face see Figure 21.2,
- addition of a new vertex splitting a given edge,
- addition of a new vertex raising by one the dimension of a degenerate – lower dimensional triangulation,
- removal of a vertex incident to three faces,
- removal of a vertex lowering the dimension of the triangulation

21.3 The Default Triangulation Data Structure

CGAL provides the class `CGAL::Triangulation_data_structure_2<Vb,Fb>` as a default triangulation data structure.

21.3.1 Flexibility

In order to provide flexibility, the default triangulation data structure is templated by two parameters which stand respectively for a vertex base class and a face base class. The concept *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2* describe the requirements for the vertex and face classes of a triangulation data structure.

This design allows the user to plug in the triangulation data structure his own vertex or face classes tuned for his application.

Figure 21.3: The cyclic dependency in triangulations software design.

21.3.2 The cyclic dependency of template parameters

Since adjacency and incidence relation are stored in vertices and faces, the vertex and face classes have to know the types of handles on faces and vertices provided by the triangulation data structure. Therefore, vertex and face classes need to be templated by the triangulation data structure. Because the triangulation data structure is itself templated by the vertex and face classes this induces a cyclic dependency. See figure 21.3.

21.3.3 The rebind mechanism

The solution proposed by CGAL to resolve this cyclic dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class `std::allocator`. The vertex and face classes plugged in the instantiation of a triangulation data structure are themselves instantiated with a fake data structure. The triangulation data structure will then rebind these classes, plugging itself at the place of the fake data structure, before using them to derive the vertex and face classes. The rebinding is performed through a nested template class *Rebind.TDS* in the vertex and face class, which provide the rebound class as a type called *Other*.

Here is how it works schematically. First, here is the rebinding taking place in the triangulation data structure.

```
template < class Vb, class Fb >
class Triangulation_data_structure
{
```

```

typedef Triangulation_data_structure<Vb,Fb>    Self;

// Rebind the vertex and face base to the actual TDS (Self).
typedef typename Vb::template Rebind_TDS<Self>::Other  VertexBase;
typedef typename Fb::template Rebind_TDS<Self>::Other  FaceBase;

// ... further internal machinery leads to the final public types:
public:
    typedef ...  Vertex;
    typedef ...  Face;
    typedef ...  Vertex_handle;
    typedef ...  Face_handle;
};

```

Then, here is the vertex class with its nested *Rebind_TDS* template class and its template parameter set by default to an internal type faking a triangulation data structure.

```

template < class TDS = an internal type faking a triangulation data
structure >
class Vertex_base
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef Vertex_base<TDS2>    Other;
    };
    ...
};

```

Imagine an analog *Face_base* class. The triangulation data structure is then instantiated as follows :

```

typedef Triangulation_data_structure< Vertex_base<>, Face_base<> > TDS;

```

21.3.4 Making use of the flexibility

There are several possibilities to make use of the flexibility offered by the triangulation data structure.

- First, when the user needs to have, in vertices and faces, additional information which do not depend on types defined by the triangulated data structure, predefined classes *Triangulation_vertex_base_with_info* and *Triangulation_face_base_with_info* can be plugged in. Those classes have a template parameter *Info* to be instantiated by a user defined type. They store a data member of this type and gives access to it.
- Second, the user can derive his own base classes from the default base classes : *Triangulation_ds_vertex_base_2*, and *Triangulation_ds_face_base_2* are the default base classes to be plugged in a triangulation data structure used alone. Triangulation classes requires a data structure in which other base classes have been plugged in. The default base classes for most of the triangulation classes are *Triangulation_vertex_base_2*, and *Triangulation_face_base_2* are the default base classes to be used when the triangulation data structure is plugged in a triangulation class.

When derivation is used, the rebinding mechanism is slightly more involved, because it is necessary to rebind the base class itself. However the user will be able to use in his classes references to types provided by the triangulation data structure. For example,

```

template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt> >
class My_vertex_base
    : public Vb
{
public :
    template < typename TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<Gt,Vb2>                            Other;
    };

    typedef typename Vb::Triangulation_data_structure    Tds;
    typedef typename Tds::Vertex_handle                  Vertex_handle;
    .....
};

```

- At last the user can write his own base classes. If the triangulation data structure is used alone, the requirements for the base classes are described by the concepts *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2*, documented page [1476](#) and page [1471](#). If the triangulation data structure is plugged into a triangulation class, the concepts for the vertex and base classes depends on the triangulation class. The most basic concepts, valid for basic and Delaunay triangulations are *TriangulationVertexBase_2* and *TriangulationFaceBase_2*, documented page [1426](#) and page [1422](#).

See section [20.11](#) for examples of using the triangulation data structure flexibility.

2D Triangulation Data Structure Reference Manual

Sylvain Pion and Mariette Yvinec

The triangulation data structure can be seen as a container for the faces and vertices of a triangulation. This class also takes care of all the combinatorial operations performed on the triangulation.

The class `CGAL::Triangulation_data_structure_2<Vb,Fb>` is a model of the concept `TriangulationDataStructure_2`, which includes the subconcepts `TriangulationDataStructure_2::Face` and `TriangulationDataStructure_2::Vertex`.

To ensure all the **flexibility** of the triangulation classes, described and in Section 20.11 of Chapter 20, the model `CGAL::Triangulation_data_structure_2<Vb,Fb>` has two templates parameters. The class `CGAL::Triangulation_data_structure_2<Vb,Fb>` derives its `Vertex` and `Face` types from the two template parameters `Vb` and `Fb` respectively.

If the triangulation data structure is used alone, these parameters have to be instantiated by models of the concepts `TriangulationDSFaceBase_2` and `TriangulationDSVertexBase_2`. These concepts are described in this chapter together with their default models `CGAL::Triangulation_ds_face_base_2<Tds>` and `CGAL::Triangulation_ds_vertex_base_2<Tds>`.

If the triangulation data structure is plugged into a triangulation class, the parameters have to be instantiated by models of different refining concepts according to the actual type of the triangulation. These refining concepts and their models are described in Chapter 20

TriangulationDataStructure_2

Definition

The concept `TriangulationDataStructure_2` describes the requirements for the second template parameter of the basic triangulation class `Triangulation_2<Traits,Tds>` and of all other 2D triangulation classes.

The concept can be seen as a container for the faces and vertices of the triangulation. The concept `TriangulationDataStructure_2` includes two subconcepts `TriangulationDataStructure_2::Vertex` and `TriangulationDataStructure_2::Face`, described respectively page 1478 and page 1474.

The `TriangulationDataStructure_2` maintains incidence and adjacency relations among vertices and faces.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

Each edge has two implicit representations : the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the `neighbor(i)` of f . See Figure 20.2

The triangulation data structure is responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure allows to perform some combinatorial operations on the triangulation and guarantees the maintainance on proper incidence and adjacency relations among the vertices and faces. The term combinatorial operations means that those operations are purely topological and do not depend on the geometric embedding. Insertion of a new vertex in a given face, or in a given edge, suppression of a vertex of degree three, flip of two edges are examples of combinatorial operations.

Types

<code>TriangulationDataStructure_2::size_type</code>	Size type (unsigned integral type)
<code>TriangulationDataStructure_2::difference_type</code>	Difference type (signed integral type)
<code>TriangulationDataStructure_2::Vertex</code>	The vertex type. Requirements for this type are described in concept <code>TriangulationDataStructure_2::Vertex</code> page 1478.
<code>TriangulationDataStructure_2::Face</code>	The face type. Requirements for this type are described in concept <code>TriangulationDataStructure_2::Face</code> page 1474.

Vertices and faces are accessed via `Vertex_handle` and `Face_handle`. These types are models of the concept `Handles` which basically supports the two dereference operators `*` and `->`.

<code>TriangulationDataStructure_2::Vertex_handle</code>	Handle to a vertex
<code>TriangulationDataStructure_2::Face_handle</code>	Handle to a face.
<code>typedef std::pair<Face_handle,int> Edge;</code>	The edge type. The <code>Edge(f,i)</code> is edge common to faces f and $f.neighbor(i)$. It is also the edge joining the vertices <code>vertex(cw(i))</code> and <code>vertex(ccw(i))</code> of f .

The following iterators allow one to visit all the vertices, edges and faces of a triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_2:: Face_iterator
TriangulationDataStructure_2:: Edge_iterator
TriangulationDataStructure_2:: Vertex_iterator

The following circulators allow to visit all the edges or faces incident to a given vertex and all the vertices adjacent to a given vertex. They are all bidirectional and non mutable.

TriangulationDataStructure_2:: Face_circulator
TriangulationDataStructure_2:: Edge_circulator
TriangulationDataStructure_2:: Vertex_circulator

Iterators and circulators are convertible to the corresponding handles, thus they can be passed directly as argument to the functions expecting a handle.

Creation

TriangulationDataStructure_2 tds; default constructor.

TriangulationDataStructure_2 tds(tds1); Copy constructor. All the vertices and faces are duplicated.

TriangulationDataStructure_2& tds = tds1

Assignment. All the vertices and faces of *tds1* are duplicated in *tds* . Former faces and vertices of *tds* , if any, are deleted

Vertex_handle tds.copy_tds(tds1, Vertex_handle v = Vertex_handle())

tds1 is copied into *tds*. If *v != NULL*, the vertex of *tds* corresponding to *v* is returned, otherwise *Vertex_handle()* is returned.

Precondition: The optional argument *v* is a vertex of *tds1*.

void tds.swap(& tds1) Swaps *tds* and *tds1*. Should be preferred to *tds=tds1* or *tds(tds1)* when *tds1* is deleted after that.

void tds.clear() Deletes all faces and all finite vertices.

Access Functions

int tds.dimension() returns the dimension of the triangulation.
size_type

size_type tds.number_of_vertices() returns the number of vertices in the data structure.
size_type

tds.number_of_faces() returns the number of two dimensional faces in the data structure.

size_type

tds.number_of_edges()

returns the number of edges in the triangulation data structure.

size_type

tds.number_of_full_dim_faces()

returns the number of full dimensional faces, i.e. faces of dimension equal to the dimension of the triangulation. This is the actual number of faces stored in the triangulation data structure.

— *advanced* —

Setting

void tds.set_dimension(int n)

sets the dimension.

— *advanced* —

Queries

bool tds.is_vertex(Vertex_handle v)

returns true if *v* is a vertex of *tds*.

bool tds.is_edge(Face_handle fh, int i)

tests whether (fh, i) is an edge of *tds*. Answers *false* when $dimension() < 1$.

bool tds.is_edge(Vertex_handle va, Vertex_handle vb)

returns true if *va vb* is an edge of *tds*.

bool tds.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle &fr, int &i)

as previous. In addition, if true is returned *fr* and *i* are set such that the pair (fr, i) is the description of the ordered edge *va vb*.

bool tds.is_face(Face_handle fh)

tests whether *fh* is a face of *tds*. Answers *false* when $dimension() < 2$.

bool tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)

true if there is a face having *v1*, *v2* and *v3* as vertices.

bool tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)

as above. In addition, if *true* is returned, *fr* is a pointer to the face with *v1*, *v2* and *v3* as vertices.

Traversing the triangulation

Face_iterator tds.faces_begin()

visits all faces

Face_iterator tds.faces_end()

Vertex_iterator tds.vertices_begin()

visits all vertices

Vertex_iterator tds.vertices_end()

<i>Edge_iterator</i>	<i>tds.edges_begin()</i>	visits all edges
<i>Edge_iterator</i>	<i>tds.edges_end()</i>	

Three circulator classes allow to traverse the edges or faces incident to a vertex or the vertices adjacent to this vertex.. A face circulator is invalidated by any modification of the face it points to. An edge circulator is invalidated by any modification of anyone of the two faces incident to the edge pointed to. A vertex circulator that turns around vertex v and that has as value a pointer to vertex w , is invalidated by any modification of anyone of the two faces incident to v and w .

<i>Vertex_circulator</i>	<i>tds.incident_vertices(Vertex_handle v, Face_handle f=NULL)</i>
--------------------------	--------------------------------------------------------------------

Precondition: If the face f is given, it has to be incident to be a face of tds incident to v and the circulator begins with the vertex $f->vertex(ccw(i))$ if i is the index of v in f .

<i>Edge_circulator</i>	<i>tds.incident_edges(Vertex_handle v, Face_handle f=NULL)</i>
------------------------	-----------------------------------------------------------------

Precondition: If the face f is given, it has to be a face of tds incident to v and the circulator begins with the edge $(f,cw(i))$ of f if i is the index of v in f .

<i>Face_circulator</i>	<i>tds.incident_faces(Vertex_handle v, Face_handle f=NULL)</i>
------------------------	-----------------------------------------------------------------

Precondition: If the face f is given, it has to be a face of tds incident to v and the circulator begins with the face f .

<i>Vertex_handle</i>	<i>tds.mirror_vertex(Face_handle f, int i)</i>
----------------------	-------------------------------------------------

returns vertex of $f->neighbor(i)$.

<i>int</i>	<i>tds.mirror_index(Face_handle f, int i)</i>
------------	------------------------------------------------

returns the index of f as a neighbor of $f->neighbor(i)$.

Modifiers

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

<i>void</i>	<i>tds.flip(Face_handle f, int i)</i>	exchanges the edge incident to f and $f->neighbor(i)$ with the other diagonal of the quadrilateral formed by f and $f->neighbor(i)$.
-------------	----------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------

<i>Vertex_handle</i>	<i>tds.insert_first()</i>	creates the first vertex and returns a pointer to it.
<i>Vertex_handle</i>	<i>tds.insert_second()</i>	creates the second vertex and returns a pointer to it.

<i>Vertex_handle</i>	<i>tds.insert_in_edge(Face_handle f, int i)</i>	adds a vertex v splitting edge i of face f . Return a pointer to v .
----------------------	--------------------------------------------------	------------------------------------------------------------------------------

<i>Vertex_handle</i>	<i>tds.insert_in_face(Face_handle f)</i>	adds a vertex v splitting face f in three. Face f is modified, two new faces are created. Return a pointer to v
----------------------	-------------------------------------------	-------------------------------------------------------------------------------------------------------------------------

Figure 21.4: Flip.

Figure 21.5: Insertion

Vertex_handle *tds.insert_dim_up(Vertex_handle w, bool orient=true)*

adds a vertex v , increasing by one the dimension of the triangulation. Vertex v and the existing vertex w are linked to all the vertices of the triangulation. The boolean *orient* decides the final orientation of all faces. A pointer to vertex v is returned.

void *tds.remove_degree_3(Vertex_handle v, Face *f=NULL)*

removes a vertex of degree 3. Two of the incident faces are destroyed, the third one is modified. If parameter f is specified, it has to be a face incident to v and will be the modified face.

Precondition: Vertex v is a finite vertex with degree 3 and, if specified, face f is incident to v .

void *tds.remove_second(Vertex_handle v)*

removes the before last vertex.

void *tds.remove_first(Vertex_handle v)*

removes the last vertex.

void *tds.remove_dim_down(Vertex_handle v)*

removes vertex v incident to all other vertices and decreases by one the dimension of the triangulation.

Precondition: if the dimension is 2, the number of vertices is more than 3, if the dimension is 1, the number of vertices is 2.

————— *advanced* —————

The following modifiers are required for convenience of the advanced user. They do not guarantee the combinatorial validity of the resulting triangulation.

```
template< class EdgeIt>
Vertex_handle    tds.star_hole( EdgeIt edge_begin, EdgeIt edge_end)
```

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end[$. Returns a pointer to the vertex.

```
template< class EdgeIt, class FaceIt>
Vertex_handle    tds.star_hole( EdgeIt edge_begin, EdgeIt edge_end, FaceIt face_begin, FaceIt face_end)
```

same as above, except that, to build the new faces, the algorithm first recycles faces in the sequence $[face_begin, face_end[$ and create new ones when the sequence is exhausted.

```
template< class EdgeIt>
void             tds.star_hole( Vertex_handle v, EdgeIt edge_begin, EdgeIt edge_end)
```

uses vertex v to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end[$.

```
template< class EdgeIt, class FaceIt>
void             tds.star_hole( Vertex_handle v,
                               EdgeIt edge_begin,
                               EdgeIt edge_end,
                               FaceIt face_begin,
                               FaceIt face_end)
```

same as above, recycling faces in the sequence $[face_begin, face_end[$.

```
void             tds.make_hole( Vertex_handle v, List_edges& hole)
```

removes the vertex v , and store in $hole$ the list of edges on the boundary of the hole.

```
Vertex_handle    tds.create_vertex()           adds a new vertex.
Face_handle      tds.create_face( Face_handle f1, int i1, Face_handle f2, int i2, Face_handle f3, int i3)
```

adds a face which is the neighbor $i1$ of $f1$, $i2$ of $f2$ and $i3$ of $f3$.

```
Face_handle      tds.create_face( Face_handle f1, int i1, Face_handle f2, int i2)
```

adds a face which is the neighbor $i1$ of $f1$, and the neighbor $i2$ of $f2$.

```
Face_handle      tds.create_face( Face_handle f1, int i1, Vertex_handle v)
```

adds a face which is the neighbor $i1$ of $f1$, and has v as vertex.

```
Face_handle      tds.create_face( Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)
```

adds a face with vertices $v1$, $v2$ and $v3$.

<i>Face_handle</i>	<i>tds.create_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle f1, Face_handle f2, Face_handle f3)</i>	adds a face with vertices <i>v1</i> , <i>v2</i> and <i>v3</i> , and neighbors <i>f1</i> , <i>f2</i> , <i>f3</i> .
<i>Face_handle</i>	<i>tds.create_face()</i>	adds a face whose vertices and neighbors are set to NULL.
<i>void</i>	<i>tds.delete_face(Face_handle)</i>	deletes a face.
<i>void</i>	<i>tds.delete_vertex(Vertex_handle)</i>	deletes a vertex.

└────────── advanced ─────────┘

Miscellaneous

<i>int</i>	<i>tds.ccw(int i)</i>	returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>tds.cw(int i)</i>	returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>tds.is_valid()</i>	checks the combinatorial validity of the triangulation: call the <i>is_valid()</i> member function for each vertex and each face, checks the number of vertices and the Euler relation between numbers of vertices, faces and edges.
<i>size_type</i>	<i>tds.degree(Vertex_handle v)</i>	Returns the degree of <i>v</i> in the triangulation.

I/O

The information output in the *ostream* is: the dimension, the number of (finite) vertices, the number of (finite) faces. Then comes for each vertex, the non combinatorial information stored in that vertex if any. Then comes for each face, the indices of its vertices and the non combinatorial information (if any) stored in this face. Then comes for each face again the indices of the neighboring faces. The index of an item (vertex or face) the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

<i>void</i>	<i>tds.file_output(ostream& os, Vertex_handle v = Vertex_handle(), bool skip_first=false)</i>	writes <i>tds</i> into the stream <i>os</i> . If <i>v</i> is not a null handle, vertex <i>v</i> is output first or skipped if <i>skip_first</i> is true.
<i>Vertex_handle</i>	<i>tds.file_input(istream& is, bool skip_first=false)</i>	inputs <i>tds</i> from file and returns a pointer to the first input vertex. If <i>skip_first</i> is true, it is assumed that the first vertex has been omitted when output.

istream& *istream*& *is* >> *TriangulationDataStructure_3* & *tds*

reads a combinatorial triangulation from *is* and assigns it to
tds

ostream& *ostream*& *os* << *TriangulationDataStructure_3* *tds*

writes *tds* into the stream *os*

TriangulationDSFaceBase_2

Definition

The concept `TriangulationDSFaceBase_2` describes the requirements for the base face of a *Triangulation_data_structure_2* <Vb.Fb>.

Note that if the *Triangulation_data_structure_2* is plugged into a triangulation class, the face base class may have additional geometric requirements depending on the triangulation class.

At the base level, (see Sections 20.3 and 21.3), a face stores handles on its three vertices and on the three neighboring faces. The vertices and neighbors are indexed 0, 1 and 2. Neighbor i lies opposite to vertex i .

Since the *Triangulation_data_structure_2* is the class which defines the handle types, the face base class has to be somehow parameterized by the triangulation data structure. But since the *Triangulation_data_structure_2* itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a *Triangulation_data_structure_2* use a *void* as triangulation data structure parameter. Then, the *Triangulation_data_structure_2* uses a *rebind* mechanism (similar to the one specified in *std::allocator*) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the *Triangulation_data_structure_2* actually uses as a base class for the class *Triangulation_data_structure_2::Face*.

Types

The concept `TriangulationDSFaceBase_2` has to provide the following types.

```
TriangulationDSFaceBase_2:: template <typename TDS2> struct Rebind_TDS;
```

This nested template class has to define a type *Other* which is the *rebound* face base, where the *Triangulation_data_structure_2* is actually plugged in. This type *Other* will be the actual base of the class *Triangulation_data_structure_2::Face*.

```
typedef TriangulationDataStructure_2 Triangulation_data_structure;
typedef TriangulationDataStructure_2::Vertex_handle Vertex_handle;
typedef TriangulationDataStructure_2::Face_handle Face_handle;
```

Creation

TriangulationDSFaceBase_2 *f*; default constructor.
TriangulationDSFaceBase_2 *f*(*Vertex_handle* v0, *Vertex_handle* v1, *Vertex_handle* v2);

Initializes the vertices with $v0$, $v1$, $v2$ and the neighbors with *Face_handle*()).

TriangulationDSFaceBase_2 *f*(*Vertex_handle* *v0*,
 Vertex_handle *v1*,
 Vertex_handle *v2*,
 Face_handle *n0*,
 Face_handle *n1*,
 Face_handle *n2*)

initializes the vertices with *v0*, *v1*, *v2* and the neighbors with
n0, *n1*, *n2*.

Access Functions

<i>int</i>	<i>f.dimension()</i>	returns the dimension.
<i>Vertex_handle</i>	<i>f.vertex(int i)</i>	returns the vertex <i>i</i> of <i>f</i> . Precondition: $0 \leq i \leq 2$.
<i>bool</i>	<i>f.has_vertex(Vertex_handle v)</i>	returns true if <i>v</i> is a vertex of <i>f</i> .
<i>bool</i>	<i>f.has_vertex(Vertex_handle v, int& i)</i>	as above, and sets <i>i</i> to the index of <i>v</i> in <i>f</i> .
<i>int</i>	<i>f.index(Vertex_handle v)</i>	returns the index of <i>v</i> in <i>f</i> .
<i>Face_handle</i>	<i>f.neighbor(int i)</i>	returns the neighbor <i>i</i> of <i>f</i> . Precondition: $0 \leq i \leq 2$.
<i>bool</i>	<i>f.has_neighbor(Face_handle n)</i>	returns true if <i>n</i> is a neighbor of <i>f</i> .
<i>bool</i>	<i>f.has_neighbor(Face_handle n, int& i)</i>	as above, and sets <i>i</i> to the index of <i>n</i> in <i>f</i> .
<i>int</i>	<i>f.index(const Face_handle n)</i>	returns the index of neighbor <i>n</i> in <i>f</i> .

Setting

<i>void</i>	<i>f.set_vertex(int i, Vertex_handle v)</i>	sets vertex <i>i</i> to <i>v</i> . Precondition: $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_vertices()</i>	sets the vertices to <i>Vertex_handle()</i> .
<i>void</i>	<i>f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)</i>	sets the vertices.
<i>void</i>	<i>f.set_neighbor(int i, Face_handle n)</i>	sets neighbors <i>i</i> to <i>n</i> . Precondition: $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_neighbors()</i>	sets the neighbors to <i>Face_handle()</i> .
<i>void</i>	<i>f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)</i>	sets the neighbors.

Orientation

<i>void</i>	<i>f.reorient()</i>	Changes the orientation of <i>f</i> by exchanging <i>vertex(0)</i> with <i>vertex(1)</i> and <i>neighbor(0)</i> with <i>neighbor(1)</i> .
<i>void</i>	<i>f.ccw_permute()</i>	performs a counterclockwise permutation of the vertices and neighbors of <i>f</i> .
<i>void</i>	<i>f.cw_permute()</i>	performs a clockwise permutation of the ver- tices and neighbors of <i>f</i> .

Checking

bool *f.is_valid(bool verbose = false)*

performs any required test on a face.
If *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

Various

*void** *f.for_compact_container()*
void&* *f.for_compact_container()*

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Face

Definition

The concept `TriangulationDataStructure_2::Face` describes the types used to store the faces face class of a *TriangulationDataStructure_2*, see page [1463](#). A `TriangulationDataStructure_2::Face` stores three pointers to its three vertices and three pointers to its three neighbors. The vertices are indexed 0,1, and 2 in counterclockwise order. The neighbor indexed i lies opposite to vertex i .

In degenerate cases, when the triangulation data structure stores a simplicial complex of dimension 0 and 1, the type `TriangulationDataStructure_2::Face` is used to store the faces of maximal dimension of the complex : i.e. a vertex in dimension 0, an edge in dimension 1. Only vertices and neighbors with index 0 are set in the first case, only vertices and neighbors with index 0 or 1 are set in the second case.

Types

The class `TriangulationDataStructure_2::Face` defines the same types as the triangulation data structure except the iterators and the circulators.

Creation

The methods *create_face* and *delete_face()* have to be used to define new faces and to delete non longer used faces.

Vertex Access Functions

<i>Vertex_handle</i>	<i>f.vertex(int i)</i>	returns the vertex i of f . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.index(Vertex_handle v)</i>	returns the index of vertex v in f . <i>Precondition:</i> v is a vertex of f
<i>bool</i>	<i>f.has_vertex(Vertex_handle v)</i>	returns <i>true</i> if v is a vertex of f .
<i>bool</i>	<i>f.has_vertex(Vertex_handle v, int& i)</i>	returns <i>true</i> if v is a vertex of f , and computes the index i of v in f .

Neighbor Access Functions

The neighbor with index i is the neighbor which is opposite to the vertex with index i .

<i>Face_handle</i>	<i>f.neighbor(int i)</i>	returns the neighbor i of f . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.index(Face_handle n)</i>	returns the index of face n . <i>Precondition:</i> n is a neighbor of f .
<i>bool</i>	<i>f.has_neighbor(Face_handle n)</i>	returns <i>true</i> if n is a neighbor of f .
<i>bool</i>	<i>f.has_neighbor(Face_handle n, int& i)</i>	returns <i>true</i> if n is a neighbor of f , and compute the index i of n .

Setting

<i>void</i>	<i>f.set_vertex(int i, Vertex_handle v)</i>	sets vertex <i>i</i> to be <i>v</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_neighbor(int i, Face_handle n)</i>	sets neighbor <i>i</i> to be <i>n</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_vertices()</i>	sets the vertices pointers to <i>NULL</i> .
<i>void</i>	<i>f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)</i>	sets the vertices pointers.
<i>void</i>	<i>f.set_neighbors()</i>	sets the neighbors pointers to <i>NULL</i> .
<i>void</i>	<i>f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)</i>	sets the neighbors pointers.

Checking

<i>bool</i>	<i>f.is_valid()</i>	returns <i>true</i> if the function <i>is_valid()</i> of the base class returns <i>true</i> and if, for each index <i>i</i> , $0 \leq i < 3$, face <i>f</i> is a neighbor of its neighboring face <i>neighbor(i)</i> and shares with this neighbor the vertices <i>cw(i)</i> and <i>ccw(i)</i> in correct reverse order.
-------------	---------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Miscellaneous

<i>int</i>	<i>f.ccw(int i)</i>	Returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.cw(int i)</i>	Returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.

I/O

<i>istream&</i>	<i>istream& is >> &f</i>	Inputs any non combinatorial information possibly stored in the face.
<i>ostream&</i>	<i>ostream& os << f</i>	Outputs any non combinatorial information possibly stored in the face.

TriangulationDSVertexBase_2

Definition

The concept `TriangulationDSVertexBase_2` describes the requirements for the vertex base class of a `Triangulation_data_structure_2<Vb,Fb>`.

Note that if the `Triangulation_data_structure_2` is plugged into a triangulation class, the vertex base class has additional geometric requirements depending on the triangulation class.

At the base level, provides access to one of its incident face through a *Face_handle*.

Since the `Triangulation_data_structure_2` is the class which defines the handle types, the vertex base class has to be somehow parameterized by the triangulation data structure. But since the `Triangulation_data_structure_2` itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a `Triangulation_data_structure_2` use a *void* as triangulation data structure parameter. Then, the `Triangulation_data_structure_2` uses a *rebind* mechanism (similar to the one specified in `std::allocator`) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS2>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the `Triangulation_data_structure_2` actually uses as a base class for the class of `Triangulation_data_structure_2::Vertex`.

Refines

`TriangulationDataStructure_2::Vertex`

Types

The concept `TriangulationDSVertexBase_2` has to provide the following types.

`TriangulationDSVertexBase_2::template <typename TDS2> struct Rebind_TDS;`

This nested template class has to define a type *Other* which is the *rebound* vertex base , where the actual `Triangulation_data_structure_2` is plugged in. This type *Other* will be the actual base of the class `Triangulation_data_structure_2::Vertex`.

<code>typedef TriangulationDataStructure_2</code>	<code>Triangulation_data_structure;</code>
<code>typedef TriangulationDataStructure_2::Vertex_handle</code>	<code>Vertex_handle;</code>
<code>typedef TriangulationDataStructure_2::Face_handle</code>	<code>Face_handle;</code>

Creation

<code>TriangulationDSVertexBase_2 v;</code>	default constructor.
<code>TriangulationDSVertexBase_2 v(Face_handle f);</code>	Constructs a vertex pointing to face <i>f</i> .

Various

```
void*          v.for_compact_container()
void*&         v.for_compact_container()
```

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Vertex

Definition

The concept `TriangulationDataStructure_2::Vertex` describes the type used by a *TriangulationDataStructure_2* to store the vertices, see page [1463](#).

Some of the requirements listed below are of geometric nature and are *optional* when using the triangulation data structure class alone. They became required when the triangulation data structure is plugged into a triangulation.

Types

The class `TriangulationDataStructure_2::Vertex` defines the same types as the triangulation data structure except the iterators.

TriangulationDataStructure_2::Vertex::Point *Optional for the triangulation data structure used alone.*

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Access Functions

<i>Point</i>	<i>v.point()</i>	returns the geometric information of <i>v</i> .
<i>Face_handle</i>	<i>v.face()</i>	returns a face of the triangulation having <i>v</i> as vertex.

————— *advanced* —————

Setting

<i>void</i>	<i>v.set_point(Point p)</i>	sets the geometric information to <i>p</i> .
<i>void</i>	<i>v.set_face(Face_handle f)</i>	sets the incident face to <i>f</i> .

————— *advanced* —————

Checking

<i>bool</i>	<i>v.is_valid(bool verbose = false)</i>
-------------	-------------------------------------------

Checks the validity of the vertex. Must check that its incident face has this vertex. The validity of the base vertex is also checked. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

I/O

istream& *istream*& *is* >> & *v* Inputs the non-combinatorial information possibly stored in the vertex.

ostream& *ostream*& *os* << *v* Outputs the non combinatorial operation possibly stored in the vertex.

TriangulationDataStructure_2

Modifiers

In addition to the modifiers required by the *TriangulationDataStructure_2* concept, the *Triangulation_data_structure_2<Vb,Fb>* class supports also the modifiers below. Note also that the modifiers below guarantee the combinatorial validity of the resulting data structure.

<i>Vertex_handle</i>	<i>tds.join_vertices(Face_handle f, int i)</i>	Joins the vertices that are endpoints of the edge (f,i) . It returns a vertex handle to common vertex (see Fig. 21.6). <i>Precondition:</i> f must be different from <i>Face_handle()</i> and i must be 0, 1 or 2.
<i>Vertex_handle</i>	<i>tds.join_vertices(Edge e)</i>	Joins the vertices that are endpoints of the edge e . It returns a vertex handle to common vertex.
<i>Vertex_handle</i>	<i>tds.join_vertices(Edge_iterator eit)</i>	Joins the vertices that are endpoints of the edge $*eit$. It returns a vertex handle to common vertex.
<i>Vertex_handle</i>	<i>tds.join_vertices(Edges_circulator ec)</i>	Joins the vertices that are endpoints of the edge $*ec$. It returns a vertex handle to common vertex.

```
boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>
```

```
tds.split_vertex( Vertex_handle v, Face_handle f1, Face_handle f2 )
```

Splits the vertex v into two vertices $v1$ and $v2$. The common faces f and g of $v1$ and $v2$ are created after (in the counter-clockwise sense) the faces $f1$ and $f2$. The 4-tuple $(v1,v2,f,g)$ is returned (see Fig. 21.6).
Precondition: *dimension()* must be equal to 2, $f1$ and $f2$ must be different from *Face_handle()* and v must be a vertex of both $f1$ and $f2$.

<i>Vertex_handle</i>	<i>tds.insert_degree_2(Face_handle f, int i)</i>	Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle f and the integer i is duplicated. It returns a handle to the vertex created (see Fig. 21.7).
----------------------	----------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

`void tds.remove_degree_2(Vertex_handle v)`

Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of v that are not incident to it are collapsed (see Fig. 21.7).

Precondition: The degree of v must be equal to 2.

Figure 21.6: The join and split operations.

Figure 21.7: Insertion and removal of degree 2 vertices.

CGAL::Triangulation_ds_face_base_2<Tds>

Definition

The class *Triangulation_ds_face_base_2<Tds>* is a model for the concept *TriangulationDSFaceBase_2* to be used by *Triangulation_data_structure_2*.

CGAL::Triangulation_ds_vertex_base_2<Tds>

Definition

The class *Triangulation_ds_vertex_base_2* can be used as the base vertex for a *Triangulation_data_structure_2*, it is a model of the concept *TriangulationDSVertexBase_2*.

This base class can be used directly or can serve as a base to derive other base classes with some additional attributes (a color for example) tuned for a specific application.

Note that if the *Triangulation_data_structure_2* is used as a parameter of a geometric triangulation, there are additional geometric requirements to be fulfilled by the vertex base class, and *Triangulation_ds_vertex_base_2* cannot be plugged in.

The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in \mathbb{R}^3 . It is a partition of the convex hull of A into tetrahedra whose vertices are the points of A . Together with

the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of \mathbb{R}^3 . Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

22.1 Representation

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

The class `Triangulation_3<TriangulationTraits_3, TriangulationDataStructure_3>` of CGAL implements this point of view and therefore considers the triangulation of the set of points as a set of finite and infinite tetrahedra. Notice that the infinite vertex has no significant coordinates and that no geometric predicate can be applied on it.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space \mathbb{R}^3 (see Figure 22.1). The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

Figure 22.1: Orientation of a cell (3-dimensional case).

As in the underlying combinatorial triangulation (see Chapter 23), edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex with index i) and an edge is given by a cell and two indices (the edge (i,j) of a cell c is the edge whose endpoints are the vertices of c with indices i and j). See Figure 23.1.

Degenerate Dimensions The class `Triangulation_3` can also deal with triangulations whose dimension d is less than 3. A triangulation of a set of points in \mathbb{R}^d covers the whole space \mathbb{R}^d and consists of cells having $d + 1$ vertices: some of them are infinite, they are obtained by linking the additional infinite vertex to each facet of the convex hull of the points.

- *dimension 2*: when a triangulation only contains coplanar points (which is the case when there are only three points), it consists of triangular faces.
- *dimension 1*: the triangulation contains only collinear points (which is the case when there are only two points), it consists of edges.
- *dimension 0*: the triangulation contains only one finite point.
- *dimension -1*: this is a convention to handle the case when the only vertex of the triangulation is the infinite one.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered (0, 1, 2); edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate dimensions (*i.e.* dimensions < 3): in dimension 2, each cell has only one facet of index 3, and 3 edges (0, 1), (1, 2) and (2, 0); in dimension 1, each cell has one edge (0, 1).

Validity A triangulation of \mathbb{R}^3 is said to be *locally valid* iff

- (a)-(b) Its underlying combinatorial graph, the triangulation data structure, is *locally valid* (see Section 23.1 of Chapter 23)
- (c) Any cell has its vertices ordered according to positive orientation. See Figure 22.1.

When the triangulation is degenerated into a triangulation of dimension 2, the geometric validity reduces to:

(c-2D) For any two adjacent triangles (u, v, w_1) and (u, v, w_2) with common edge (u, v) , w_1 and w_2 lie on opposite sides of (u, v) in the plane.

When all the points are collinear, this condition becomes:

(c-1D) For any two adjacent edges (u, v) and (v, w) , u and w lie on opposite sides of the common vertex v on the line.

The *is_valid()* method provided in *Triangulation_3* checks the local validity of a given triangulation. This does not always ensure global validity [MNS⁺96, DLPT98] but it is sufficient for practical cases.

22.2 Delaunay Triangulation

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

Delaunay triangulations have the specific *empty sphere property*, that is, the circumscribing sphere of each cell of such a triangulation does not contain any other vertex of the triangulation in its interior. These triangulations are uniquely defined except in degenerate cases where five points are cospherical. Note however that the CGAL implementation computes a unique triangulation even in these cases.

This implementation is fully dynamic: it supports both insertions of points and vertex removal. The user is advised to use the class *Triangulation_hierarchy_3* in order to benefit from an increased efficiency for large data sets.

22.3 Regular Triangulation

The class *Regular_triangulation_3* implements incremental regular triangulations, also known as weighted Delaunay triangulations.

Let $S^{(w)}$ be a set of weighted points in \mathbb{R}^3 . Let $p^{(w)} = (p, w_p)$, $p \in \mathbb{R}^3$, $w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z)$, $z \in \mathbb{R}^3$, $w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius w_p . The *power product* between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z . $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* iff $\Pi(p^{(w)}, z^{(w)}) = 0$ (see Figure 22.2).

Figure 22.2: Orthogonal weighted points (picture in 2D).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. The weighted point orthogonal to three weighted points in the plane defined by these three points is called the *power circle*. The *power segment* will denote the weighted point orthogonal to two weighted points on the line defined by these two points.

A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)}, z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

The regular triangulation of $S^{(w)}$ is in fact the projection onto \mathbb{R}^3 of the convex hull of the four-dimensional points $(p, \|p - O\|^2 - w_p)$, for $p^{(w)} = (p, w_p) \in S^{(w)}$. Note that all points of $S^{(w)}$ do not necessarily appear as vertices of the regular triangulation. To know more about regular triangulations, see for example [ES96].

When all weights are 0, power spheres are nothing more than circumscribing spheres, and the regular triangulation is exactly the Delaunay triangulation.

22.4 Triangulation Hierarchy

The class *Triangulation_hierarchy_3* implements a triangulation augmented with a data structure that allows fast point location queries. Thus, it allows fast construction of the triangulation. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

22.5 Software Design

The main classes *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3* are connected to each other by the derivation diagram shown in Figure 22.3. This diagram also shows two other classes: *Triangulation_utils_3* (page 1597), which provides a set of tools operating on the indices of vertices in cells, and *Triangulation_hierarchy_3*, which implements a hierarchy of triangulations suitable for speeding up point location.

Figure 22.3: Derivation diagram of the 3D triangulation classes.

The three main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) provide high-level geometric functionality such as location of a point in the triangulation [DPT02], insertion and possibly removal of a point [DT03], and are responsible for the geometric validity. They are built as layers on top of a triangulation data structure, which stores their combinatorial structure. This separation between the geometry and the combinatorics is reflected in the software design by the fact that these three triangulation classes take two template parameters :

- the **geometric traits** class, which provides the type of points to use as well as the elementary operations on them (predicates and constructions). The concepts for these parameters are described in more details in Section 22.5.1 and in page 1534.
- the **triangulation data structure** class, which stores their combinatorial structure, described in Section 23.2 of Chapter 23.

The class *Triangulation_hierarchy_3* is parameterized by a class, which at the moment can only be *Delaunay_triangulation_3*. It fetches its geometric traits from this parameter directly.

22.5.1 The Geometric Traits Parameter

The first template parameter of the triangulation class *Triangulation_3*<*TriangulationTraits_3*, *TriangulationDataStructure_3*> is the geometric traits class, described by the concept *TriangulationTraits_3*. It must define the types of the geometric objects (points, segments, triangles and tetrahedra) forming the

triangulation together with a few geometric predicates on these objects: orientation in space, orientation in case of coplanar points, order of collinear points.

In addition to the requirements described before, the geometric traits class of *Delaunay_triangulation_3* must define predicates to test for the *empty sphere property*. It is described by the concept *DelaunayTriangulationTraits_3*, which refines *TriangulationTraits_3*.

The kernels provided by CGAL: *Cartesian*, *Homogeneous*, *Simple_cartesian*, *Simple_homogeneous* and *Filtered_kernel* can all be used as models for the geometric traits parameter. They supply the user with all the functionalities described for the concepts *TriangulationTraits_3* (page 1534) and *DelaunayTriangulationTraits_3* (page 1536). In addition, the predefined kernels *Exact_predicates_inexact_constructions_kernel* (page ??) and *Exact_predicates_exact_constructions_kernel* (page ??) can also be used, the later being recommended when the dual construction is used.

In order to be used as the traits class for *Regular_triangulation_3*, a class must provide functions to compute the *power tests* (see Section 22.3). *Regular_triangulation_euclidean_traits_3<K,Weight>* is a traits class designed to be used by the class *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*. It provides *Weighted_point*, a class for weighted points needed by the regular triangulation, which derives from the three dimensional point class *K::Point_3*. It supplies the user with all the functionalities described for the concept *RegularTriangulationTraits_3* (page 1539). It can be used as a traits class for *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*.

Note that for regular triangulations, plugging a filtered kernel such as *Exact_predicates_inexact_constructions_kernel* or *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_3<K,Weight>* will in fact not provide exact predicates since the weighted points and the predicates on them are not defined in the CGAL kernels. To solve this, there is also another model of the traits concept, *Regular_triangulation_filtered_traits_3<FK>*, which is providing filtered predicates (exact and efficient). The argument *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

22.5.2 The Triangulation Data Structure Parameter

The second template parameter of the main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) is a triangulation data structure class. This class can be seen as a container for the cells and vertices maintaining incidence and adjacency relations (see Chapter 23). A model of this triangulation data structure is *Triangulation_data_structure_3* (page 1594), and it is described by the *TriangulationDataStructure_3* concept (page 1573). This model is itself parameterized by a vertex base and a cell base classes, which gives the possibility to customize the vertices and cells used by the triangulation data structure, and hence by the geometric triangulation using it. Depending on the kind of triangulation used, the requirements on the vertex and cell base classes vary, and are expressed by various concepts, following the refinement diagram shown in Figure 22.4.

A default value for the triangulation data structure parameter is provided in all the triangulation classes, so it need not be specified by the user unless he wants to use a different triangulation data structure or a different vertex or cell base class.

22.5.3 Flexibility of the Design

In order to satisfy as many uses as possible, a design has been selected that allows to exchange different parts to meet the users' needs, while still re-using a maximum of the provided functionalities. We have already seen that the main triangulation classes are parameterized by a geometric traits class and a triangulation data structure (TDS), so that each of them can be interchanged with alternate implementations.

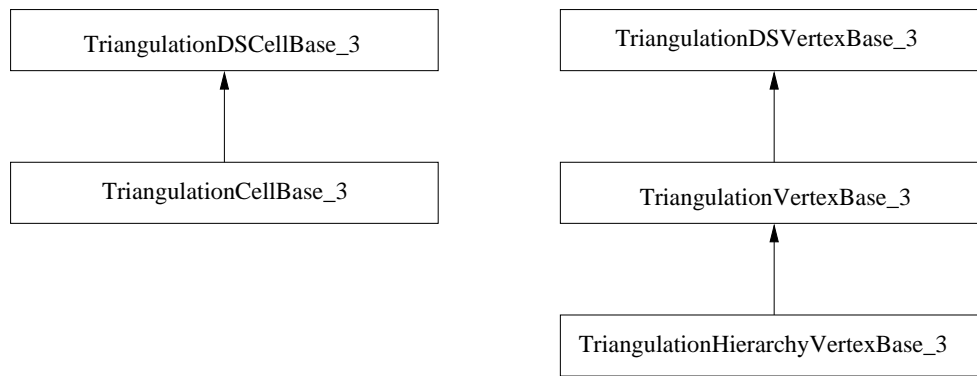

Figure 22.4: Concepts refinement hierarchy for the vertex and cell base classes parameters.

The most useful flexibility is the ability given to the user to add his own data in the vertices and cells by providing his own vertex and cell base classes to *Triangulation_data_structure_3*. The Figure 22.5 shows in more detail the flexibility that is provided, and the place where the user can insert his own vertex and/or cell base classes.

22.5.4 Backward compatibility

Starting with CGAL release 3.0, the design of the triangulation data structure has been changed in order to give the possibility to store handles (an entity akin to pointers) directly in the vertex and cell base classes. Previously, `void*` pointers were stored there instead, and later converted internally to handles, but this happened to be too restrictive for some uses.

The difference is visible to the user when he provides his own vertex or cell base class. Previously, something like the following had to be written:

```

...
template < class GT >
class My_vertex
  : public Triangulation_vertex_base<GT>
{
  typedef Triangulation_vertex_base<GT> Vb;
public:
  typedef typename Vb::Point          Point;

  My_vertex() {}
  My_vertex(const Point&p)              : Vb(p) {}
  My_vertex(const Point&p, void *c)    : Vb(p, c) {}
  ...
};

typedef Cartesian<double>                               GT;
typedef Triangulation_data_structure_3<My_vertex<GT>,
                                     Triangulation_cell_base_3<GT> > My_TDS;
typedef Triangulation_3<GT, My_TDS>                               Tr;
...

```

While now, there are three possibilities. The simplest one is to use the class *Triangulation_vertex_base_with_*

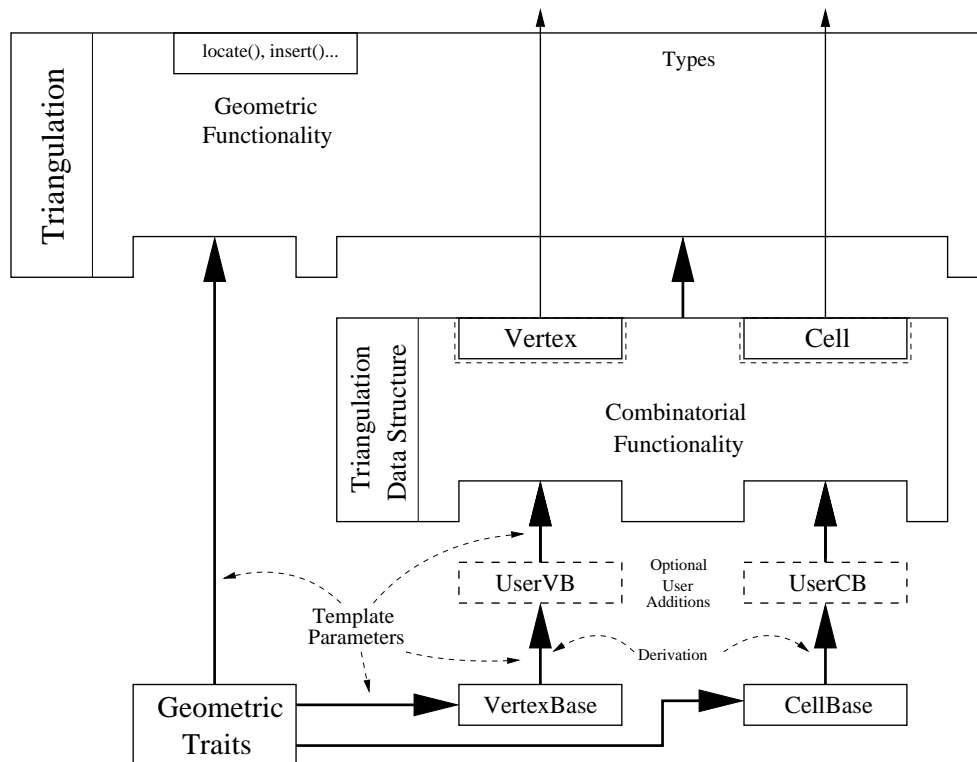

Figure 22.5: Triangulation software design.

info_3, and this approach is illustrated in a following subsection 22.6.2. The most complicated one, and probably useless for almost all cases, is to write a vertex base class from scratch, following the documented requirements. This is mostly useless because most of the time it is enough to derive from the models that CGAL provides, and add the desired features. In this case, when the user needs to access some type that depends on the triangulation data structure (typically handles), then he should write something like:

```

...
template < class GT, class Vb = Triangulation_vertex_base<GT> >
class My_vertex
: public Vb
{
public:
    typedef typename Vb::Point          Point;
    typedef typename Vb::Cell_handle    Cell_handle;

    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other Vb2;
        typedef My_vertex<GT, Vb2>                               Other;
    };

    My_vertex() {}
    My_vertex(const Point&p) : Vb(p) {}
    My_vertex(const Point&p, Cell_handle c) : Vb(p, c) {}
...
};

```

```
... // The rest has not changed
```

The changes that need to be made are the following:

- *My_vertex* is now parameterized by the vertex base class it derives from.
- a nested template class *Rebind_TDS* must be defined.
- `void*` must be changed to *Cell_handle*, and you need to extract the *Cell_handle* type from the vertex base class that *My_vertex* derives from.

The situation is exactly similar for cell base classes. Section [23.2](#) provides more detailed information.

22.6 Examples

22.6.1 Basic example

This example shows the incremental construction of a 3D triangulation, the location of a point and how to perform elementary operations on indices in a cell. It uses the default parameter of the *Triangulation_3* class.

```
// examples/Triangulation_3/example_simple.C

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <cassert>
#include <list>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Cell_handle    Cell_handle;
typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Locate_type    Locate_type;
typedef Triangulation::Point          Point;

int main()
{
    // construction from a list of points :
    std::list<Point> L;
